Formula for Strength of Rope

At the Bureau of Standards laboratories tests have been made that have resulted in a formula quickly determining the strength of rope.

For three-strand regular lay manila rope from $\frac{1}{2}$ to $4\frac{1}{2}$ in. in diameter, the following computation will give the breaking load of the rope: The average breaking load in pounds equals 5,000 multiplied by the diameter of the rope in inches, multiplied by the diameter of the rope increased by 1.

This will give, of course, the average maximum weight that the rope will hold, but the working load that may be applied with proper safety and precaution would be considerably less than the load given by the formula.

Other data on rope are contained in the Bureau of Standards Technologic Paper 198, by A. H. Stang and L. R. Strickenberg, which has just been issued.

Superpower System for the Boston-Washington Region

THE United States Geological Survey has just published Professional Paper 123 (255 pages) embodying the report of W. S. Murray and others on the Superpower System for the region between Boston, Mass., and Washington, D. C.

Congress has appropriated during the fiscal year 1921 the sum of \$125,000 "For the survey of power production and distribution in the United States, including the study of methods for the further utilization of water power and the special investigation of the possible economy of fuel, labor and materials resulting from the use in the Boston-Washington industrial region of a comprehensive system for the generation and distribution of electricity to transportation lines and industries, and the preparation of reports thereon." An additional sum of \$26,000 was contributed by thirty-six corporations and individuals, representing utilities and industries in the superpower zone. The work was promptly organized and an engineering staff was selected by Mr. Murray, consulting engineer, of New York City, who was appointed by the Secretary of the Interior to head this engineering study. The investigation was begun on July 1, 1920, and completed within a year. Some of the principal facts brought out in the report are presented in the following paragraphs.

THE SUPERPOWER ZONE

The "superpower zone" may be described as lying between the thirty-ninth and forty-fourth parallels of latitude and extending from the coast approximately 150 miles inland, embracing parts of the States of Maine, New Hampshire, Vermont, New York, Pennsylvania, Delaware and Maryland and all of the States of Massachusetts, Rhode Island, Connecticut and New Jersey. Within this zone is concentrated one-fourth of the population of the United States, and within it are operated, most of them independently, 315 electric utilities, 18 railroads and 96,000 industrial plants.

The superpower zone has relatively small hydro-electric resources and maximum industrial-power requirements. Fortunately some of the best coal deposits in the country lie near this great industrial territory, and a prime economic purpose should be so to conjoin the hydro-electric supply of power to the steam-electric supply as to produce a maximum of energy for a minimum investment of capital and a minimum operating expense, and at the same time to conserve the rapidly disappearing cheap fuels of the Appalachian coal fields.

The superpower system comprehends also a plan of power production that includes the generation of electricity by steam at tidewater and on inland waters where a sufficient quantity of condensing water can be obtained, and also the utilization of all hydro-electric power that may be economically obtainable from rivers within the zone or within transmission distance of it. The electric power so generated will be co-ordinated through a system of inter-connected transmission lines, the potentials of which will be on the order of 220,000 and 110,000 volts.

PRESENT POWER PLANTS IN THE SUPERPOWER ZONE

Under the present independent operation of the electric utilities and the manufacturing industries in the superpower zone the existing power plants are numerous and small. The average capacity of the 558 elec-

tric-utility plants now in operation in the zone is 7,900 kw., and that of the steam-electric plants 10,000 kw., while the hydro-electric plants average only 2,800 kw. Out of the 96,000 industrial establishments in the superpower zone 76,000 use power, and each of these isolated plants averages about 350 hp. Under the superpower system, by contrast, the number of power stations required to supply the entire zone in 1930 will be only 273, of which 218 will belong to the existing electric utilities. The capacity of the base-load steam plants will range from 60,000 to 300,000 kw. In none of these plants will there be installed a turbo generator having a capacity of less than 30,000 kw.

LOCATION OF POWER STATIONS AND LOAD CENTERS

The new power stations and load centers will be so located with reference to the existing electric-utility plants that are to be incorporated in the system as to insure the maximum aggregate economy in power generation and transmission. A prime object to be attained in the superpower plan is the maximum economic utilization of existing generation and transmission equipment. In the early stages, while the superpower system is taking form, existing electric-utility capacity will predominate. Indeed, in 1930, as much as 31 per cent of the total superpower capacity will be contained in plants belonging to the present electric-utility companies.

The fundamental information required for the determination of the mechanical power-supply equipment and fuel used by all the industries necessarily had to be procured from the Bureau of the Census, if for no other reason because time would not have permitted its independent compilation. The analysis of this information showed that in 1919 the equivalent of 9,311,440,000 kw.-hr. was developed by prime movers operated by the industries themselves and that 3,338,800,000 kw.-hr. was purchased. It further shows that it would have been economical to shut down 4,008,200 hp. of prime movers and purchase energy to the amount of 5,623,800,000 kw.-hr., which would have made a total of 8,962,600,000 kw.-hr. purchased in 1919. The saving in coal thus effected would have been 13,502,100 tons—71 per cent of the coal used by the industries for producing power, or 25 per cent of all the coal used by the industries.

REDUCING COST BY INTERCONNECTING SYSTEMS

In general it has been found that industrial establishments which require 500 hp. or less can economically purchase energy. Only those that need more than 500 hp. and that have special requirements for heat can generate their own power economically, and even these should have central-station connections to take up irregularities of load. The efficiency of power production by isolated industrial plants is precluded from any considerable improvement by their necessarily small average capacity.

A careful study of the power requirement for industrial establishments in the superpower zone has been made and has shown that by 1930 an annual saving of \$190,000,000 can be made to the industries themselves above the fixed charges against an investment of \$185,000,000 for the motor equipment necessary to utilize the power.

Of great interest is the economic relation established between the joint use of steam and water power. It is shown that steam and water power can be so combined

as to yield annually \$69,550,000 on an increased investment of only \$44,838,000. Here is exemplified one of the prime advantages of superpower production, costs being reduced by means of the interconnecting system which permits the highest economy in steam-produced power together with the maximum use of water power.

HYDRO-ELECTRIC POWER

The construction of a hydro-electric plant is economically justified if it produces its power at a cost less than that of a steam-electric plant of the same capacity. With maximum development of water power, however, the hydro-electric energy available within the superpower zone will amount to less than 20 per cent of the total electric power required in 1930.

Of especial importance in determining the location and capacity of the new water-power plants for the zone is the economy attained by the development of rivers beyond their primary power. The principal rivers which can contribute water power to the superpower zone are the Potomac, Susquehanna, Delaware, Hudson and Connecticut. It is proposed to utilize power from these rivers in 1930 to the following extent:

River	Capacity, Kw.	Output (Millions of Kw.-Hr.)	Investment	Production Cost (Mills per Kw.-Hr.)
Potomac.....	200,000	950	\$22,000,000	3.36
Susquehanna.....	185,000	1,230	28,000,000	3.22
Delaware.....	350,000	1,250	51,500,000	5.95
Hudson.....	150,000	900	38,350,000	5.84
Connecticut.....	165,000	760	29,000,000	5.45

The water powers of Niagara and St. Lawrence rivers are within transmission distance of the superpower zone, but on account of the time required for construction on the St. Lawrence and of the treaty restrictions concerning the use of the water at Niagara Falls the power from these sources has not been considered available in the zone prior to 1930.

The reproduction cost of the 451,500 kw. of existing hydro-electric capacity within the zone is \$87,127,000. The new hydro-electric capacity which should be installed by 1930 will bring the total capacity up to 1,501,500 kw., of which the old plants will represent 30 per cent. In 1930 the total hydro-electric investment will be \$245,977,000, of which the old plants will represent 35 per cent.

RECOMMENDED PROCEDURE

The order in which the superpower steam-electric and hydro-electric power plants and transmission systems should be constructed must depend (1) on the present industrial demand for energy that cannot be satisfied because of the difficulties of the local electric utilities in financing extensions; and (2) on the future demand for energy that will result from the more economical generation of power under the superpower system. Many of the economies incident to superpower operation will be effected through the interconnection of existing plants and systems, and these economies should be increased as new power plants and interconnections are added.

By keeping in mind the two conditions, it is believed that the quickest return will be obtained by following in chronologic sequence the order of procedure as follows:

1. The construction of a steam-electric plant near Pittston, Pa., to supply a part of its energy to the Anthracite division of the superpower zone and the remainder to the Metropolitan division, particularly New Jersey.

2. The construction of a steam-electric plant near Sunbury, Pa., to supply a part of its energy to the Anthracite division, a part to the Reading load center, and the remainder to Philadelphia.

3. The construction of hydro-electric plants on Delaware and Susquehanna rivers to supplement the steam plants indicated above.

4. The progressive development of the Hudson River projects to meet the growth of energy requirement at the Schenectady, Utica, Poughkeepsie and Pittsfield load centers.

5. The construction of a steam-electric plant near Boston to supply the Boston, Lowell and Newburyport load centers.

6. The construction of a steam-electric plant near New Haven to supply the New Haven, Bridgeport, Waterbury and Norwich load centers.

7. The partial construction of the first hydro-electric plant in the development of Potomac River as soon as the power demands of the Baltimore and Washington load centers require additional plant capacity.

Plant capacities are not stated above, as they cannot be finally determined except by further and more detailed study of local conditions combined with regional demands. The load growth at all the centers, however, will make it imperative to provide new plant capacity at an early date, so that the construction of additional plants must be started promptly after the plants that will yield the greatest return have been built.

ADVANTAGES OF SUPERPOWER ENERGY

The market for superpower energy will be furnished by the electric utilities, the industries and the railroads. The estimated requirement for energy supplied through the electric utilities for municipal, private, industrial and railroad purposes in 1930 is 31,000,000,000 kw.-hr. This energy could be supplied by a co-ordinated power system at an annual cost of \$239,000,000 less than by an unco-ordinated system such as is now in use. This amount represents the net saving after the necessary fixed charges on total capital expenditure have been deducted. The total investment in generating and transmission facilities for the superpower system will be \$1,109,564,000, of which \$416,346,000 will represent the value of existing facilities to be incorporated into the system.

A study of the 96,000 manufacturing establishments operating within the superpower zone shows that by 1930, through the maximum economical use of purchased electric energy, they can save \$190,000,000 annually above the fixed annual charges against a capital investment of \$185,000,000 to provide the motor equipment necessary to receive and use the necessary electric power.

The combined capital investment necessary for the electric utilities and the industries as of 1930 therefore amounts to \$1,294,564,000, and this total investment will yield annually above the fixed charges the sum of \$429,000,000, or 33 per cent on the amount of the investment.

Within the superpower zone there are 36,000 miles of railroad measured as single track—that is, including each track of main lines, yards and sidings. Of this total about 19,000 miles can be profitably electrified, so as to yield by 1930 an annual saving of \$81,000,000 as compared with the cost of operation by steam. The capital expenditure necessary to electrify the 19,000

miles would be \$570,000,000, and the average return upon the investment would therefore be 14.2 per cent.

Studies of the operations of each load center have shown that a large quantity of coal could have been saved had superpower facilities been available in 1919. On comparing the coal rates of power production in 1919 with those of the superpower system and applying the difference to the load that will exist in 1930 we find that the coal saved annually under the superpower system may be estimated as follows:

	Short Tons
Electric utilities.....	19,149,000
Heavy-traction railroads.....	10,210,000
Manufacturing industries.....	20,625,000
Total.....	49,984,000

COAL SAVING BY CHEMICAL AND METALLURGICAL INDUSTRIES IN SUPERPOWER ZONE

Of the total quantity of coal to be saved by the superpower system, chemical and metallurgical industries would contribute the following savings:

Industry	Coal Saved in Short Tons	Industry	Coal Saved in Short Tons
Dyeing and finishing.....	34,500	Gas, illuminating and heating.....	163,000
Steel works and rolling mills	1,035,000	Petroleum refining.....	49,000
All other iron and steel products.....	1,124,400	All other chemicals.....	586,000
Tanning, currying and finishing of leather.....	10,000	Cement.....	94,000
Paper and wood pulp.....	390,000	Clay products.....	97,400
Coke, except gas-house coke	51,000	Glass products.....	27,500
Explosives.....	52,000	Metals, non-ferrous.....	199,000
		Metal products, non-ferrous	112,000
		Total.....	4,024,800

Synopsis of Recent Chemical & Metallurgical Literature

Alcoholic Fermentation as a Source of Glycerine.—In 1780 Scheele obtained glycerine by the saponification of fats with lead oxide. In 1823 Chevreul proved that glycerine is an integral part of fats in the form of an ester of the fatty acids. This has been confirmed by Pelouze and since then glycerine has been prepared commercially by saponification of fats in soap plants. During the war, due to the scarcity of fats, researches were started to prepare glycerine synthetically or by fermentation. As early as 1873 Friedel and Silva succeeded in preparing glycerine synthetically, but up to now the process has not been an industrial success. The fermentation method at first used by Pasteur has been more successful, and Dr. K. Schweizer gives in the August, 1921, issue of *Chimie et Industrie* a lengthy description of the industrial preparation of glycerine by alcoholic fermentation.

After reviewing the work of Pasteur, Laborde, Ehrlich, Rossi, Neuberg and Kerb, he outlines the facts and hypotheses concerning the intermediate products formed during alcoholic fermentation and then describes the changes in normal alcoholic fermentation which are necessary for the manufacture of glycerine as the main product. Among the methods used for the realization of these changes he gives the following:

Reduction of Trioses. Since it is known that glycerine can be obtained by the reduction of glyceric aldehyde and dioxyacetone and since these substances are supposed to be formed as intermediate products during the conversion of sugar into alcohol, it seemed logical to expect that the addition of a reducing agent during fermentation would increase the yield of glycerine. The greatest practical difficulty was to find a yeast which would function in the presence of the large quantities of salts constituting the reducing agent.

However, by the use of a yeast prepared from molasses, and a great excess of sodium sulphite, it was possible to obtain 21.3 g. glycerine from 100 g. sugar.

Change of the Reaction of the Fermentation Medium. This is best realized by introducing given quantities of sodium carbonate in the fermentation medium shortly after fermentation started. Twenty to 25 kg. of glycerine can thus be obtained per 100 kg. of sugar.

Blocking the Formation of Acetaldehyde During Fermentation. This is best realized by using sodium sulphite, which acts not only as an alkaline reagent but also as an antiseptic for the harmful bacterias resulting from the fermentation in alkaline medium. About 23 kg. of glycerine is obtained per 100 kg. of sugar.

The author then describes the method used for the extraction and purification of the formed glycerine. He concludes by suggesting that instead of starting with sugars, which are expensive, there will soon be a possibility of preparing glycerine by using hydrolyzed sawdust and waste sulphite liquor from paper mills.

Hardening of Tool Steel.—Shipley N. Brayshaw presented a paper recently before the Sheffield Association of Metallurgists and Metallurgical Chemists, and abstracted in *Iron and Coal Trades Review*, upon an ordinary carbon tool steel containing about 0.8 per cent of tungsten and about 0.2 per cent of chromium, with a change point at 738 deg. The work was mainly for the purpose of determining the effect of various heat-treatments by means of test-bars and test-cutters. Some of the cutters were badly broken; others were fairly sound; even of the sound ones some were good and some were bad so far as their strength was concerned. Yet when each group was examined it was shown that there was a clear relation between the previous heat-treatment and the behavior on hardening. The results from the whole series of 102 cutters were reasonably consistent with scarcely half a dozen exceptions; furthermore, the results were in general accord with those obtained from the test-bars before and after hardening.

It was found that for the steel in question there was a range of temperature of somewhere about 715 to 725 deg., within which with prolonged soaking the steel reached a condition which was remarkably favorable to satisfactory hardening, as was shown by the non-occurrence of hardening cracks and the fact that taps and screw gages could be hardened without change of pitch.

Mr. Brayshaw made a proposal for a standard hardening test for the purpose of ascertaining the degree of liability of a given steel to crack in hardening. He believed that the hardening of steel could be brought completely under control provided it were reasonably sound and not objectionable in analysis. Such a simple test would show whether the steel was liable to hardening cracks or not, and the degree of liability would be indicated.

Separation of Lime From Dolomite.—H. G. Schurecht, in the July *Journal of the American Ceramic Society*, publishes an exhaustive study of "The Separation of Lime From Dolomite." Magnesium carbonate in dolomite is decomposed by calcining for 1 hour at 800 deg. C. Calcium carbonate is not completely decomposed until after calcination at 960-1,040 deg. C. for 1 hour.

By adding sufficient sulphuric acid to milk of dolomite to react with the lime present, a bulky precipitate of magnesium hydroxide is formed which may be partly separated from the finer calcium sulphate by screening through a 120-mesh sieve. The residue on the screen contains about 68.3 per cent magnesium oxide and represents about 50 per cent of the original CaMgO. The best results by flotation were obtained by removing the fine material from the raw dolomite and then calcining at 920 deg. C. Wood creosote flotation oil No. 400 was found best suited for this separation. The concentrates removed by flotation, however, represent only 25 per cent of the dolomite originally treated. By leaching and screening treatment it is possible to obtain a product containing about 80 per cent MgO. This is superior to the Canadian magnesite in MgO content. By an elutriation treatment it is possible to obtain a residue containing over 85 per cent MgO and representing about 30 per cent of the original dolomite.

Current Events

in the Chemical and Metallurgical Industries

Tariff to the Fore Again

With the tax bill practically out of the way, the Senate is concentrating its interest on tariff matters. The extent to which the chemical industries are to receive protection practically will be decided during the next few weeks. The thing which is militating most against high rates on chemicals is an impression on Capitol Hill that the chemical industries have been unusually prosperous under existing rates of duty. There is also an impression that the banking interests have gained the upper hand in many chemical activities and that there is a tendency to eliminate research and experimentation in the interest of greater profits. One of the principal reasons which influenced the House committee to recommend unusual measures for the protection of the chemical industry was the very evident need of incurring large expense in research so that the new American industries might compete successfully with the long-established chemical concerns in other countries. There is an idea that many of the former leaders in the industry who built up pretentious activities, despite the lack of protection, and who had the vision to incur large expense in experimentation study, are being crowded aside by interests who are more concerned in quick profits than in the permanency of the industry.

Fertilizer Freight Rates Discussed

A reduction of 25 per cent in the freight rate on fertilizer was urged at a hearing in Washington Nov. 2 before the traffic executives of the Southern railroads. J. W. White of Atlanta, chairman of the traffic committee of the National Fertilizer Association, and John I. Tierney, Washington representative of that organization, appeared in behalf of the fertilizer industry. They contended that the fertilizer industry had reduced its prices to the point of actual loss in its effort to be helpful in the general return to more normal prices. The fertilizer used in 1921 was 59 per cent of the amount used in 1920. One of the principal causes for this decline in fertilizer use was held to be freight rates, which have contributed nothing to the liquidating process. As a result of the reduced use of fertilizer, the cotton crop is 7,000,000 bales less than would have been the case had the fields been properly fertilized, the railroad executives were told.

National Research Council Publication on Research Chemicals

Timely information with regard to research chemicals is contained in a publication being distributed gratis by the National Research Council. The pamphlet contains a list of manufacturers, as well as an alphabetical list of the several thousand of the rarer chemicals. The pamphlet also contains a list of biological stains and indicators and another list of hydrogen ion indicators. The work follows the lines of "British Research Chemicals," published by the Association of British Chemical Manufacturers.

Standardization of Paving Brick

Elimination of excess varieties and styles in paving brick is to be considered at a meeting Nov. 15 in Washington under the auspices of the Secretary of Commerce. The meeting is to be open to all interested. A preliminary survey of the situation is being made by a committee of paving brick manufacturers and a report will be submitted setting forth the facts as to the volume of the manufacture in the various sizes and styles of bricks now in use.

Chamber of Commerce Establishes Natural Resources Department

Half of the difficulties of the natural resource industries would disappear if the public were well educated in their problems. This is the opinion of W. DuB. Brookings, the head of the Natural Resources Production Department of the Chamber of Commerce of the United States. This department is preparing a very active program in an effort to render constructive service to the raw material industries. In that connection it was pointed out that this work is supplementary to that of the various trade associations. It is believed, however, that this nation-wide organization of business men can render great assistance to the industries and to the public by conducting a campaign of education intended to enlighten the public on the vital problems of natural resource activities.

The organization of the natural resources department is just being perfected. An advisory committee has been named of which C. S. Keith, the president of the Central Coal & Coke Co. of Kansas City, is chairman. The other members of the advisory committee are: J. H. Ross, president, Exchange Supply Co., Winter Haven, Fla.; J. E. Spurr, Editor, *Engineering and Mining Journal*, New York; Christy Payne, president, Peoples & Hope Natural Gas Cos., New York; E. T. Meredith, former Secretary of Agriculture, Des Moines, Iowa; Sidney J. Jennings, vice-president, United States Smelting, Mining & Refining Co., Boston, Mass.; R. V. Norris, mining engineer, Wilkes-Barre, Pa.; Van H. Manning, American Petroleum Institute, New York, and William H. Davis, president, Midcontinent Oil & Gas Association, Bartlesville, Okla.

It is the opinion of Mr. Brookings that nothing is of more importance in this day with its tendencies toward federal regulation of business than to obtain for the natural resources industries a high degree of public confidence. This, he believes, can be obtained if the public knows the real facts in regard to these industries.

American Field Service Fellowships for French Universities

The Society for American Field Service Fellowships for French Universities will offer for open competition among graduates of American colleges and other suitably qualified candidates a number of fellowships, not to exceed twenty-five, for the purpose of encouraging advanced study and research in French universities during 1922-23. The fellowships, of the annual value of \$200 and 10,000 francs, are granted for one year and are renewable for a second year. They may be awarded in thirty-one fields of study, including chemistry, engineering, geology, mathematics, physics.

Fellows will be required to sail to France not later than July 1 of the year in which the award is made, to matriculate in a French university for the following session, and to pursue studies in the field of science designated in their awards.

Applications should reach the secretary of the society not later than Jan. 1, 1922. Application blanks and full information as to qualifications, etc., may be obtained from the secretary, Dr. I. L. Kandel, 522 Fifth Ave., New York City.

Sterling Chemical Laboratory, Yale University

With the awarding of the contract for the erection of the new chemical laboratory at Yale University, New Haven, Conn., to the Thompson-Starrett Co., 49 Wall St., New York, it is proposed to commence work immediately on the structure. The new laboratory, to be known as the Sterling Chemical Laboratory, is estimated to cost \$2,000,000.

Congress of Industrial Chemistry at Paris

The first Congress of Industrial Chemistry was opened on Monday, Oct. 10, at the National Arts and Crafts Conservatoire, M. Dior, the Minister of Commerce, presiding. Many distinguished scientists and chemical experts attended, including Mme. Curie and Sir William Pope. Dr. Frederick Cottrell and Dr. Mackall represented the United States. Paul Kestner, president of the Société de Chimie Industrielle, opened the proceedings with an account of the work of the society and outlined the subjects which would come within the range of the conference.

Sir William Pope lectured on the future of organic chemistry, with special reference to the advantages which France and Britain might derive from their tropical possessions. He was presented by M. Dior at the conclusion of his lecture with the gold medal of the French Society.

Great interest was taken in the public lecture given at the Sorbonne by Georges Claude on his method of obtaining synthetic ammonia. The lecture was illustrated both by lantern slides and experiments, M. Claude actually producing synthetic ammonia in the hall. This manufacture, he said, as carried out at the Montereau works, where pressures up to 1,000 atmospheres are used, is incomparably less dangerous than might be supposed, since by reason of the high pressures employed the parts of the apparatus used in the Claude process are so small that an explosion, as proved by experience, does no damage. Moreover, the ammonium salt (ammonium chloride) produced by the French methods is non-explosive, so no disasters similar to that of Oppau need be feared.

Lectures were also given by M. Matignon, professor at the Collège de France, on the state and development of the nitrogen industries and by M. Gall on the French cyanamide industry.

Henri Le Chatelier, member of the Institute of France, lecturing on chemical analysis, emphasized the necessity of supplementing laboratory experiments by experiments in the industrial field and pleaded for an improved system of teaching chemical analysis and for some standardization of methods of analysis.

An exhibition of applied chemistry was held in connection with the conference.

Plants Resuming Operations Growing in Number

Glassware.—The F. C. Wheaton Co., Millville, N. J., manufacturer of druggists' glass specialties, has resumed operations at its plant, effective Oct. 31, placing its furnace, the largest in south Jersey, in service.

The Potomac Glass Co., Cumberland, Md., has resumed production with a full operating force, totaling about 250 workers, following a shut-down since July.

The Hazel-Atlas Glass Co., Wheeling, W. Va., manufacturer of fruit jars, etc., has placed an additional tank in service at its Clarksburg, W. Va., works, effective Oct. 31, giving employment to about 200 additional employees and bringing operations up to a point of approximately 28 per cent of the full quota of 850 workers that are employed in normal times.

The Whitall-Tatum Co., Millville, N. J., manufacturer of druggists' glassware, has placed a new amber glass tank in operation at its Glasstown works, giving employment to additional workers. The lamp department at the works has been started up at full capacity.

The American Window Glass Co., Belle Vernon, Pa., has resumed operations at its local plant, following a six-months shut-down. It is said that orders on hand insure capacity production for some months to come.

Paper.—The International Paper Co., 30 Broad St., has increased production at its mills to about 700 tons of paper per day, or close to 60 per cent of capacity. A total of eleven mills are now operating and it is planned to resume at other mills at an early date.

The Dryden Pulp & Paper Co., Montreal, Que., is now operating at capacity, with the sulphite mill producing about 70 tons of material a day, the kraft paper mill about 13 tons daily, and the paper board mill running at close to capacity.

Rubber.—The Mason Tire & Rubber Co., Kent, Ohio, is

operating at full capacity, with three shifts. The output totals about 11,000 casings a week.

The Boston Woven Hose & Rubber Co., Boston, Mass., is now operating at close to 70 per cent of normal, with the hose-manufacturing department, comprising about 20 per cent of the total output at the works, producing at 75 per cent of normal. The tape, heel, tube and matting departments are increasing their operating schedules. Effective Nov. 1, wages at the mill have been reduced 5 to 15 per cent, with the average labor reduction at 10 per cent.

Oil.—The Sinclair Consolidated Oil Corporation, 45 Nassau St., New York, operating refineries in Indiana, Kansas and Oklahoma, will place all plants on a capacity basis of production at once.

Coke.—The H. C. Frick Coke Co., a subsidiary of the United States Steel Corporation, has placed 350 coke ovens in blast at its plants at Calumet, Southwest and Hostetter, Pa., closely following the resumption of operations at the Continental No. 1 and York Run plants of the company, totaling 600 ovens, on Oct. 24. This total of 950 ovens will give employment to over 1,200 men. The ovens have been banked since last spring. It is planned to place 300 ovens at the Brownsville, Pa., works in operation at an early date.

Steel.—The Superior Sheet Steel Co., Canton, Ohio, is operating at full capacity, with eight mills in service.

The Cumberland Steel Co., Cumberland, Md., has agreed with operatives at the plant for production on a two-shift, full-time basis, each shift to work three 10-hour days a week. The men have accepted a wage reduction of 10 per cent.

The Tyler Tube & Pipe Co., Washington, Pa., has resumed operations at its plant. Orders on hand are said to insure continuous production throughout the fall and winter.

Iron.—The Reading Iron Co. is arranging for the immediate resumption of its Keystone blast furnace, Reading, Pa., with a weekly output totaling 2,000 tons.

Chemical.—The Solvay Process Co., Syracuse, N. Y., is now operating at close to normal pre-war production at its Solvay works, manufacturing soda ash and its derivatives. Early in the summer the plants were on a 40 per cent capacity basis.

Lower Freight Rates Sought for Pottery Products

Representative pottery interests at Trenton, N. J., and vicinity are formulating plans to bring about an early readjustment and lowering of freight rates on commodities entering into the manufacture of sanitary pottery, including clay, feldspar, flint, etc. It is held that these materials are now defraying more than their just proportion of the transportation burden of the country and that a reduction in rates will stimulate greatly business in the sanitary ware line. A committee has been appointed to compile data and carry out the details of the movement. M. D. Warren, traffic manager of the Chamber of Commerce, Trenton, will act as chairman of the committee; other members include: Charles Brian, general manager of the Paper Makers' Chemical Co., Easton, Pa.; George Dyer, representing the Sanitary Potters' Association, Trenton; John Manor, Golding Sons' Co., East Liverpool, Ohio; A. C. Hoffman, Trenton Potteries Co., Trenton; L. L. Lee, Star Porcelain Co., Trenton; F. W. Walker, secretary, Beaver Falls Art Tile Co., Beaver Falls, Pa.; and Charles Donnelly, United States Potters' Association, Pittsburgh, Pa.

A.S.M.E. Meeting to Stress Elimination of Industrial Waste

Elimination of industrial waste will be stressed at the annual meeting of the American Society of Mechanical Engineers to be held in New York City, Dec. 5 to 9. The report of the Committee on Elimination of Waste in Industry of the American Engineering Council will provide the basis for the discussion, which will emphasize the engineering phases of the waste problem. The A.S.M.E., in arranging its annual meeting program, follows the recommendations of the committee that each technical society give intensive treatment to the report.

Personal

ALLEN ABRAMS has resigned as research associate from the research laboratory of applied chemistry at the Massachusetts Institute of Technology to become chief chemist for the Cornell Wood Products Co., Cornell, Wis.

Dr. CHARLES BASKERVILLE, College of the City of New York, gave an interesting address recently on the subject of chemical research, before a joint meeting of the Rhode Island Branch of the American Chemical Society and the Providence Engineering Society, at Brown University, Providence, R. I.

Dr. CHARLES H. HERTY has resigned as editor of the *Journal of Industrial and Engineering Chemistry* of the American Chemical Society to accept the presidency of the newly organized Synthetic Organic Chemical Manufacturers Association.

ALBERT HIRSCH has been appointed general sales manager of the Atriken Chemical Works, New Brunswick, N. J.

GEORGE E. HOFFMAN of the Trenton Potteries Co., Trenton, N. J., gave an interesting address on the subject of "Fine Pottery Manufacture" before the members of the Rotary Club, Allentown, Pa., at their noon-day meeting, Oct. 21.

JOHN F. MILLER of Pittsburgh, vice-president of the Westinghouse Air Brake Co., Pittsburgh, has been elected an alumni trustee of the College of Wooster, Wooster, Ohio, filling an unexpired term in the class of 1922. Mr. Miller graduated from the college in 1881.

WILLIAM WHISTLER MILLS, for five years assistant chief chemist of the Pittsburgh Crucible Steel Co. at its Midland, Pa., works, has been added to the faculty of the College of Wooster, Wooster, Ohio, as instructor in chemistry. Mr. Mills resigned from the Pittsburgh Crucible Steel Co. in 1919 to take up graduate work at Ohio State University, Columbus, Ohio, which he completed last June with the degree of Master of Science.

OLIVER C. RALSTON has been promoted from the position of superintendent of the Mining Experiment Station of the Bureau of Mines, Seattle, Wash., to assistant chief metallurgist with headquarters at Berkeley, Cal. He will also act as superintendent of the Pacific Experiment Station of the Bureau of Mines.

EDWIN R. THEIS, formerly chemist for the American Leather Co., Cincinnati, Ohio, has joined the staff of the department of leather research, College of Engineering and Commerce, University of Cincinnati, as research chemist.

The members of the technical staff of the American delegation to the Conference on the Limitation of Armament who were selected for their industrial and scientific knowledge are: Dr. Edgar F. Smith, president of the American Chemical Society; General C. C. Williams, Chief of Ordnance; General Amos A. Fries, Chief, Chemical Warfare Service; General George O. Squier, Chief, Signal Corps; William S. Culbertson, United States Tariff Commission; Dr. S. W. Stratton, Director, Bureau of Standards; J. H. Dellinger, Chief, Radio Investigations, Bureau of Standards; L. W. Austin, Radio Specialist, Navy Department. The other members of the technical staff are specialists in international law, international relations, or in army and navy operations.

Obituary

JOHN BOYD DUNLOP, Dublin, Ireland, known as the inventor of the pneumatic rubber tire, died on Oct. 24. He was eighty-one years old.

WILLIAM H. PRICE, secretary of Griffith & Turner, Baltimore, Md., fertilizer manufacturers, died recently at the age of sixty-six years.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Nov. 7, 1921.

Chemical activity continued to show increased signs of improvement and conditions in most directions were of a decidedly favorable character. The discontinuance of the proposed railroad strike did not have a bad effect on the demand for the more important commodities.

Buyers are more eager to anticipate their standing contracts and are covering requirements a month or two in advance. This condition was more pronounced last week than at any time during the year. Consumers that have accustomed themselves to small quantity buying have again been picking up large quantities of odd resale material from the spot market and the tendency of values has remained quite firm throughout the list.

Heavy importations of chemicals were noted during the week. These undoubtedly were shipments ordered a month or two ago and had no disastrous effect on spot quotations, as the bulk of this material is going directly to various consuming interests. Domestic producers have found it extremely difficult to keep up with the increasing demand, and efforts are being made to expand operations as much as possible.

Among the outstanding features of the week was the sudden rise of barium chloride. Prussiate of soda, cyanide of soda and caustic potash were items that attracted considerable attention from large consumers and the market has shown a gradual advance during the entire week. Prussiate of soda and barium chloride closed higher for shipment from abroad. Solid caustic soda and soda ash remained steady, with a tendency to advance. Oxalic acid still feels the pinch of keen competition existing among producers, and quotations were lower at the close. Bichromate of soda has ruled steady, with orders reported in larger volume. Consumers of muriate of potash have shown more interest at the recently reduced figures. Bleaching powder has also shown a regular steady outlet, although large quantities were recently imported from Germany.

CHEMICALS

Spot prices for imported 88-92 per cent caustic potash were a trifle firmer during the latter part of the week. Importations have been quite heavy, but consumers seem to be constantly in the market for additional quantities. While several sellers quoted the market at 6½c. per lb., the majority of holders named 6¼c. as their lowest figure. Shipment material was obtainable at 5¾c. per lb. Importers of calcined carbonate of potash, 80-85 per cent, quote 4½c. per lb. for spot material. There are not as many offerings around the market as were noted a week ago and it is understood that some large sellers are very low on supplies. The 85-90 per cent test is quoted at 4¾c. per lb., while the 99 per cent U.S.P. is quoted at 15c. per lb. Foreign powdered chlorate of potash is offered for shipment at 5¼c. per lb. c.i.f. New York. Some sellers demanded as high as 5¾c. The spot market is somewhat unsettled on imported material, with sellers asking 6½@7½c. per lb. for the powdered and 8c. for the crystals. Manufacturers of domestic chlorate quote the market unchanged at 12c. per lb. f.o.b. works. Importers offered muriate of potash on the basis of \$37@37.50 per ton of 80 per cent KCl, c.i.f., New York. Buyers are showing a keener interest in the new prices and considerable business has been reported. Yellow prussiate of potash is moving in a small way at 20½c. per lb. The general quotation heard among leading factors is 20½@21½c. per lb., depending upon quantity. The red variety is inactive and sellers quote the market at 28c. per lb.

There has been no departure from the upward tendency of yellow prussiate of soda during the past week. Buyers are eager to pay higher prices for spot material, but offerings are very scarce. Sales at the close were reported at 14¾c. per lb. In some places as high as 15c. was named for spot ma-

terial. Shipments were quoted at 14½c. per lb. for November-December. *Bichromate of soda* sold at 8c. per lb. during the beginning of the week and was fractionally higher at the close. A carload lot was reported sold at 7½c., but this was an inside transaction and did not represent the general range. Quotations were around 8½c. per lb. for standard brand goods. The demand is showing a moderate improvement with consumers more eager to follow the market activity. Sales of solid *caustic soda* have been made at \$4.10@4.20 per 100 lb. for standard material. A good inquiry was experienced for less than carload quantities. Producers have received numerous orders for large lots, but claim to be entirely sold out for prompt shipment. Buyers of *amyl acetate* are covering actual requirements in the market, but are not inclined to extend commitments at the present time. Producers quote the market for commercial at \$2.40@\$2.70 per gal., the price varying according to quantity and sellers.

Dealers of crude *fusel oil* quote the market at \$1.50@\$1.60 per gal. The imported material has sold at about the same figures as the domestic, although an occasional stray lot has been found at a concession. It is stated that prices abroad are higher than those prevailing in the open market. The refined grade is quoted by producers at \$2.60@\$3 per gal. Odd lots have been sold through dealers down to \$2.40 per gal., but in most instances, this material was not up to specifications. There was some improvement noted in the call for *arsenic*, and prices ranged from 6@6½c. per lb. for the white, powdered material. Some sellers of *nitrite of soda* were fractionally higher in their views and quoted the spot market at 7@7½c. per lb. Buyers, in general, were interested only in small quantities and were not eager to pay over 6½c. per lb. Closing prices for domestic *oxalic acid* at the works were somewhat lower and producers were quoting 12½c. per lb. Dealers reported sales ex-store at 13½@14c. per lb. The market is still feeling the influence of strong competition from first-hand interests.

COAL-TAR PRODUCTS

Reports from various steel factories of more pronounced activity put a brighter aspect on existing conditions for *benzene* and consumers feel more reassured about supplies. Coke-oven operations showed another gain, but this will not be reflected in the *benzene* market for at least another month. The spot market was practically bare of supplies, with quotations on odd lots heard at 40c. per gal. The intermediate market is showing decidedly improved signs of activity owing to the improved condition of the dye field and sales are more numerous in various quarters. The demand for *cresylic acid* is not very active, but the market seems to be holding its own at 65c. per gal. for the 95 per cent and 70c. for the 97-99 per cent. A round lot sale of the 95 per cent was reported at slightly under the quoted figure, but most sellers are adhering to the regular price. Activity in *naphthalene flakes* continued to a moderate extent, but the balls were somewhat dormant. Prime white flakes sold at 6¼@7½c. per lb. Makers ask up to 8½c. per lb., but most business is going to jobbers at the lower figures. Buying in *phenol* for domestic consumption increased to a considerable degree and some large-quantity sales were made at 9½c. per lb. Odd lots at lower prices were occasionally offered around the market, but the quality is known to be of an inferior grade. Official Government resellers ask 12c. per lb. Selling in *para-phenylenediamine* has been fairly active at \$1.70@\$1.75 per lb. Inquiries at the close of the week were being recorded in good volume. Makers of *dimethylaniline* ask 45c. per lb. and upward. Resale stocks are practically unheard of around the market and first hands are the controlling influence on prices. Sales of *aniline oil* at 18c. per lb. were made in several directions during the week. The market seemed to be strengthening up somewhat and sellers are maintaining prices. Stocks of *beta-naphthol* are still quite heavy and no real snap to trading has been witnessed on this commodity in the past few months. Makers quote down to 34c. per lb., but according to various rumors have placed business well under the resale price of 32c. per lb. Prices of *H acid* in some directions were under the quotation of \$1.10 per lb. which prevailed generally.

The Chicago Market

CHICAGO, Nov. 4, 1921.

Viewing world markets over the last century and a half in relation to present commodity prices, it is noted we are on the down grade of a major commodity price cycle covering a 40- to 50-year period similar to the condition following the Napoleonic wars and the Civil War. Looking at the minor 3- to 5-year cycle, however, commodity prices show a straight precipitous drop beginning in July of last year and reaching a bottom near the middle of 1921. In other words, the curve of average commodity prices has not only been checked but actually moved upward. Chemicals, being essential raw materials of basic industries, follow very closely the average price of other commodities and vary with the industrial movements. It may be safely predicted that regardless of the possible lower prices of chemicals 10 years from now the immediate trend will be upward.

This trend is clearly shown by Chicago prices during the past fortnight. Stocks on hand are lighter, and while prices on the average have not risen to any great extent they remain very firm at present levels. Furthermore a good volume of business is enjoyed by most firms. Speculators are beginning to accumulate stocks with expectation of higher figures. Clearing of the skies on the railroad situation is removing the cause for immediate haste in purchasing. The next large movement should be upward regardless of pessimistic opinions which exist in some quarters.

INDUSTRIAL CHEMICALS

Caustic soda is very firm. Supplies are nearly depleted and prices are 4½c. for the ground 76 per cent and 4½c. for the solid. *Soda ash* is moving well, with firm price at \$2.60 per 100 lb. for material in cooperage. *Potash alum* is also in good demand, with a price of 5½c. per lb. for the lump and 6½c. for the powdered. *Sal ammoniac* remains quiet, with supplies available at 7½@7¾c. per lb. for the white granular 98-100 per cent. *Carbon tetrachloride* is in brisk demand and 10¾c. per lb. the lowest figure quoted. *Formaldehyde* is still quiet, with 12c. per lb. as the prevailing figure and a possibility of some shading. *Glycerine* remains unmoved in price and without apparent demand. Refiners are asking 14¼@14½c. per lb. for the large drums.

LIST MOSTLY UNCHANGED

The rest of the list remains about as usual. *Caustic potash* continues firm and unchanged in price, with supplies available at 6½c. per lb. for the 88-92 per cent grade. *Potassium bichromate* is quoted at 13@13½c. per lb. and the *soda* at 9½c. for single casks. A decline of 2c. per lb. was noted in some quarters on *potassium permanganate*, and U.S.P. crystals of foreign origin are now available at 21c. for small lots. *Bicarbonate of soda* is offered at \$2.60 per 100 lb. for single barrels. *Sodium fluoride* is not so active, but prices are unchanged at 11@12c. per lb., according to quantity. *Zinc sulphate* is quiet at 3½c. per lb. for the tech. cryst. in single barrel lots.

ACIDS

Acid prices remain as quoted in last letter with nominal demand. Supplies are plentiful and are said to be moving well. *Acetic acid* is firm with supplies of the 28 per cent available at \$2.65@\$2.75 per 100 lb. and glacial at \$10.25@\$10.75. *Oxalic acid* is in fair demand at 17c. per lb. *Citric* and *tartaric acids* are very quiet with domestic makers apparently in control of the market. *Hydrochloric acid* is quiet and unchanged as to price.

VEGETABLE OILS

Linseed oil is moving in a fair way with no large transactions noted. The boiled oil is offered at an increased price of 76c. per gal. and the raw at 74c.

NAVAL STORES

Turpentine is in a firm position, according to a prominent factor, and higher prices can be expected. This material was offered today at 86½c. per gal. for small quantities in drums.

The Iron and Steel Market

PITTSBURGH, Nov. 4, 1921.

The tapering off in demand for steel products generally has now developed a decidedly quiet market. Buying has not ceased, but it is materially decreased in volume, and it lacks snap entirely. While various causes are assigned for the dullness, including in particular the alleged prospect that freight rates will be reduced in the near future, the more rational view seems to be that the dullness is a reflection of the season of the year. The iron and steel market is normally dull in December and January, unless it has previously acquired great momentum, and in a generally dull period the seasonal dullness is likely to begin especially early.

It is obvious that existing ideas or impressions as to the state of business generally and of the prospects are rather vague. "Business" is commonly spoken of as a homogeneity, which it is not. The total volume of business, measured by bank clearings, bank debits, freight ton-mileage on the railroads, and similar general indices, is really fairly large. The character of the activity, however, is not such as to produce a large demand for steel. In what is called by the very general term "building" there is a rather high stage of activity, but the building is chiefly of garages and dwelling houses, which do not require much steel. The same amount of money invested in power plants, factories and skyscrapers would produce a much larger tonnage of steel demand. Again, the railroads are receiving and spending a great deal of money, but the outgo is chiefly against payrolls, not against rails, bridges, buildings, rolling stock and other improvements.

STEEL PRICES

The American Steel & Wire Co. (Steel Corporation) has been soliciting contracts from regular customers on the ground that a second price advance, following that of Sept. 12, is to be made, the September advance having been to 2.60c. for plain wire and \$2.90 for nails. The Youngstown Sheet & Tube Co., which alone among the important independents did not advance its prices in September, has this week made the advance. By other independents there has been some selling lately at the old prices, and it is not certain that a second advance can be made generally effective.

In attempting a second step in advancing prices on sheets the market has slipped a trifle on the first step. Three weeks ago independents began formally announcing a second advance of \$5 a ton, following that in September, which raised black sheets from 2.75c. to 3c., but instead of the market becoming established at 3.25c. sales have been made in the past week at less than 3c., and even 2.75c., the minimum of the market this year, has been quoted in some isolated cases.

In bars, shapes and plates there is a more competitive market than a few weeks ago, in that some mills, formerly committed to slightly advanced prices, have receded from that position and are meeting competition when the tonnage involved is important. Prices generally are in the neighborhood of 1.60c. for bars and shapes and 1.55c. for plates.

Tin plate prices have continued unsettled and may become still more unsettled. The McKeesport Tin Plate Co., with a 44-mill plant, has made an agreement with its tonnage men whereby the men accept a 20 per cent wage reduction and the company guarantees full operation of the plant to Jan. 1.

PIG IRON AND COKE

The pig-iron market continues very dull, expectations recently entertained of an improvement being wholly disappointed. In some quarters the lack of buying is attributed to expectation on the part of buyers that freight rates will be reduced, but the hand-to-mouth buying that has characterized the market for many months could hardly be affected by such expectations, and it is more reasonable to assume that actual consumption has decreased or will decrease. Quotable prices are unchanged, but are becoming more or less nominal: Bessemer, \$20; basic, \$19; foundry, \$21, f.o.b. valley furnaces, with \$1.96 freight to Pittsburgh.

Connellsville coke is somewhat softer, by the double influence of continued light demand and softer conditions in coal. Spot furnace is \$3.25@3.35, contract furnace about \$3.40 and spot foundry \$4.25@4.75, depending on brand.

Magnesium carbonate, technical.....lb.	.08 — .08½	.09 — .10
Magnesium sulphate, U. S. P.....100 lb.	2.50 — 2.75	—
Magnesium sulphate, technical.....100 lb.	—	1.10 — 1.75
Methanol, 95%.....gal.	—	.66 — .68
Methanol, 97%.....gal.	—	.70 — .72
Nickel salt, double.....lb.	—	.12 — .12½
Nickel salt, single.....lb.	—	.14 — .14½
Phosgene (see carbonyl chloride).....	—	—
Phosphorus, red.....lb.	.40 — .41	.42 — .45
Phosphorus, yellow.....lb.	—	.30 — .35
Potassium bichromate.....lb.	.10½ — .11	.11½ — .11½

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . \$. . .	\$0.25 1/2 - \$0.28
Potassium bromide, granular..... lb.		.14 - .20
Potassium carbonate, U. S. P..... lb.	.15 - .16	.17 - .20
Potassium carbonate, 80-85%..... lb.	.04 1/2 - .04 3/4	.05 - .06
Potassium chlorate, crystals..... lb.	.08 - .08 1/2	.08 1/2 - .12
Potassium cyanide..... lb.		.40 - .45
Potassium hydroxide (caustic potash)..... lb.	.06 1/2 - .06 3/4	.06 3/4 - .08
Potassium iodide..... lb.		2.60 - 2.75
Potassium nitrate..... lb.	.07 3/4 - .07 1/2	.08 - .09
Potassium permanganate..... lb.	.18 - .19	.20 - .22
Potassium prussiate, red..... lb.	.28 - .29	.29 1/2 - .30
Potassium prussiate, yellow..... lb.	.20 1/2 - .21	.21 1/2 - .22
Rochelle salts (see sodium potas tartrate).....		
Salammoniac (see ammonium chloride).....		
Sal soda (see sodium carbonate).....		
Salt cake (bulk)..... ton		20.00 - 22.00
Silver cyanide..... oz.		1.35 - 1.38
Silver nitrate..... oz.		.46 - .47
Soda ash light..... 100 lb.	2.10 - 2.15	2.20 - 2.60
Soda ash, dense..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate..... lb.	.04 - .04 1/4	.04 1/2 - .05
Sodium bicarbonate..... 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium bichromate..... lb.	.08 1/2 - .08 3/4	.08 3/4 - .08 7/8
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P..... lb.	.04 1/2 - .05	.05 1/2 - .06
Sodium borate (borax)..... lb.	.05 1/2 - .06	.06 1/2 - .07
Sodium carbonate (soda)..... 100 lb.	1.75 - 1.90	2.00 - 2.25
Sodium chl rate..... lb.	.07 1/2 - .07 3/4	.08 - .08 1/2
Sodium cyanide..... lb.	.27 1/2 - .28	.28 1/2 - .30
Sodium fluoride..... lb.	.11 - .12	.12 1/4 - .14
Sodium hydroxide (caustic soda)..... 100 lb.	4.10 - 4.15	4.20 - 4.75
Sodium hyposulphite..... lb.		.03 1/2 - .03 3/4
Sodium nitrite..... lb.	.07 - .07 1/4	.07 1/2 - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.04 1/2 - .04 3/4	.04 3/4 - .05 1/4
Sodium potassium tartrate (Rochelle salts) lb.		.21 - .24
Sodium prussiate, yellow..... lb.	.14 1/2 - .15	.15 1/2 - .15 3/4
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02 1/2 - .02 3/4	.03 - .03 1/4
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, f. sed, 60-62 per cent (conc.) lb.	.04 1/2 - .05	.05 1/2 - .05 3/4
Sodium sulphite, crystals..... lb.	.03 1/2 - .03 3/4	.04 - .04 1/4
Strontium nitrate, powdered..... lb.	.12 - .13	.13 1/2 - .20
Sulphur chl ride, red..... lb.	.05 - .05 1/2	.05 1/2 - .06 1/2
Sulphur, crude..... ton	18.00 - 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08 1/2	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	.19 1/2 - .20
Tin oxide..... lb.		.37 - .38 1/2
Zinc carbonate, precipitate..... lb.	.16 - .16 1/2	.17 - .17
Zinc chloride, gran..... lb.	.09 1/4 - .09 1/2	.10 - .11
Zinc cyanide..... lb.	.42 - .44	.45 - .47
Zinc dust..... lb.	.11 1/2 - .11	.11 1/2 - .12 1/2
Zinc oxide, XX..... lb.	.07 1/2 - .07	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 - \$1.20
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.27 - .30
Aniline oil, drums extra..... lb.	.17 1/2 - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.35 - 1.45
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.75 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.31 - .34
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 35-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.10 - 1.20
Dimethylaniline..... lb.	.45 - .60
Dinitrobenzene..... lb.	.23 - .27
Dinitrochlorobenzene..... lb.	.20 - .25
Dinitronaphthalene..... lb.	.30 - .35
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, car lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.05 - 1.15
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.65 - 1.70
Naphthalene crushed, in bbls..... lb.	.06 1/2 - .08 1/2
Naphthalene, flake..... lb.	.06 1/2 - .08 1/2
Naphthalene, balls..... lb.	.08 - .09 1/2
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlorobenzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80
Para-dichlorobenzene..... lb.	.12 - .15
Paranitroaniline..... lb.	.77 - .80
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50

Phenol, U. S. P., drums..... lb.	.09 1/2 - .12
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.00 - 2.25
Salicylic acid, tech., in bbls..... lb.	.18 - .20
Salicylic acid, U. S. P..... lb.	.19 - .22
Salol..... lb.	.60 - .70
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.21 - \$0.22
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.36 - .42
Candellilla wax..... lb.	.24 - .25
Carnauba, No. 1..... lb.	.46 - .47
Carnauba, No. 2, North Country..... lb.	.24 - .24 1/2
Carnauba, No. 3, North Country..... lb.	.14 - .15
Japan..... lb.	.22 - .22 1/2
Montan, crude..... lb.	.04 1/2 - .05
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 1/2 - .03 1/2
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 - .02
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03 1/2
Paraffine waxes, refined, 125 m.p..... lb.	.03 1/2 - .03 1/2
Paraffine waxes, refined, 128-130 m.p..... lb.	.03 1/2 - .04 1/2
Paraffine waxes, refined, 133-135 m.p..... lb.	.04 1/2 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 1/2 - .06
Stearic acid, single pressed..... lb.	.09 - .09
Stearic acid, double pressed..... lb.	.10 - .10
Stearic acid, triple pressed..... lb.	.11 - .11 1/2

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.70 - 5.70
Rosin E-I..... 280 lb.	5.70 - 5.85
Rosin K-N..... 280 lb.	6.30 - 6.75
Rosin W. G.-W. W..... 280 lb.	7.10 - 7.30
Wood rosin, bbl..... 280 lb.	6.25 - . . .
Spirits of turpentine..... gal.	.81 - . . .
Wood turpentine, steam dist..... gal.	.79 - . . .
Wood turpentine, dest. dist..... gal.	.77 - . . .
Pine tar pitch, bbl..... 200 lb.	. . . - 6.50
Tar, kila burned, bbl. (500 lb.)..... bbl.	. . . - 10.00
Retort tar, bbl..... 500 lb.	. . . - 10.00
Rosin oil, first run..... gal.	.35 - . . .
Rosin oil, second run..... gal.	.37 - . . .
Rosin oil, third run..... gal.	.44 - . . .
Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	\$1.90
Pine oil, pure, dest. dist..... gal.	1.50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr., 1.080-1.960..... gal.	.35
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35
Pinewood creosote, ref..... gal.	.52

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37
70-72 deg., steel bbls. (85 lb.)..... gal.	.35
68-70 deg., steel bbls. (85 lb.)..... gal.	.34
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.70 - 3.00
Blood, dried, f.o.b., N. Y..... unit	4.00
Bone, 3 and 50, ground, raw..... ton	30.00 - 32.00
Cyanamide, f.o.b. works..... unit	4.50
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 - 3.00
Nitrate soda..... 100 lb.	2.35 - 2.45
Tankage, high grade, f.o.b. Chicago..... unit	3.00 - 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 - 6.50
Tennessee, 78-80 p.c..... ton	8.00 - 9.00
Potassium muriate, 80 p.e..... ton	37.00 - 40.00
Potassium sulphate..... unit	1.15 - 1.20

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 - .21 1/2
Upriver coarse..... lb.	.11 1/2 - .12
Upriver caucho ball..... lb.	.11 - .12
Plantation—First latex crepe..... lb.	.15 1/2 - .15 1/2
Ribbed smoked sheets..... lb.	.15 1/2 - .15 1/2
Brown crepe, thin, clean..... lb.	.15 - . . .
Amber crepe No. 1..... lb.	.17 - . . .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 1/2 - \$0.10 1/2
Castor oil, AA, in bbls..... lb.	.11 1/2 - .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.14 1/2 - .14 1/2
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 1/2 - .09 1/2
Cocoonut oil, Cochin grade, in bbls..... lb.	.10 1/2 - .10 1/2
Corn oil, crude, in bbls..... lb.	.10 1/2 - .10 1/2
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 1/2 - .07 1/2
Cottonseed oil, summer yellow..... lb.	.09 - .09 1/2
Cottonseed oil, winter yellow..... lb.	.09 1/2 - .10

Linseed oil, raw, car lots (domestic).....	gal.	.67	—	.68
Linseed oil, raw, tank cars (domestic).....	gal.	.62	—	.63
Linseed oil, in 5-bbl lots (domestic).....	gal.	.70	—	.71
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palm, Lagos.....	lb.	.07	—	.07½
Palm, Niger.....	lb.	.06½	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.08½
Peanut oil, refined, in bbls.....	lb.	.11½	—	.11¾
Rapeseed oil, refined in bbls.....	gal.	.85	—	.87
Rapeseed oil, blown, in bbls.....	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.09	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07½	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.45	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04½
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casain.....	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04½
Chalk, Precipitated, domestic, heavy.....	lb.	.03½	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, light.....	lb.	.04½	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.06	—	.07
Graphite, Ceylon chip.....	lb.	.04½	—	.05
Graphite, high grade amorphous crude.....	lb.	.00¾	—	.02½
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr, f.o.b. N. Y.....	per ton	55.00	—	60.00
Magnesite, calcined.....	per ton	60.00	—	65.00
Pumice stone, imported.....	lb.	.03	—	.40
Pumice stone, domestic, lump.....	lb.	.05	—	.05½
Pumice stone, domestic, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.68	—	.70
Shellac, orange superfine.....	lb.	.80	—	.82
Shellac, A. C. garnet.....	lb.	.58	—	.60
Shellac, T. N.....	lb.	.68	—	.70
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	7.50	—	11.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$50.00	—	
Carborundum refractory brick, 9-in. { less than carlot	1,000	1250.00	—	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	52- 55	—	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30- 32	—	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	33- 35	—	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	35- 40	—	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30- 35	—	
Magnesite brick, 9-in. straight.....	net ton	65- 70	—	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77	—	
Magnesite brick, soaps and splits.....	net ton	98	—	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	40- 42	—	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	42- 45	—	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35- 38	—	

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.11	—

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Gadsden Clay Products Co. will build an addition to its plant, to be equipped for the manufacture of pressed bricks and other burned clay products. Work is now under way on the construction of three new kilns.

TUSCALOOSA—The proposed new company to be organized under the direction of the Industrial Committee of the local Chamber of Commerce, J. B. Brosius, secretary, for the construction and operation of a local pulp and paper mill, will be capitalized at \$2,000,000. Details of the new company and plant are being arranged.

Arkansas

EL DORADO—The Grison Refining Co. has construction under way on a new oil refinery. It is planned to establish a gasoline-producing plant in connection with the new works.

California

LOS ANGELES—The Western Pipe & Steel Co., 1670 North Broadway, has plans under way for the erection of a large plant on a 23-acre site of land acquired at Santa Fe and Slauson Aves. It will consist of a number of buildings for general steel products manufacture.

Connecticut

NEW BRITAIN—The Donnelly Brick Co. has awarded a contract to the William H. Allen Co., Inc., Hungerford Court, for the rebuilding of its plant, recently destroyed by fire. The new works will consist of a number of buildings, including drier department, tunnel kiln building, machine room and other mechanical branches.

Delaware

WILMINGTON—The Martin Leather Co., 701 East 5th St., has filed plans for the erection of a new 2-story building on East 5th St., near Spruce St., 47 x 60 ft. The company recently increased its capital from \$700,000 to \$1,500,000.

Florida

MARIANNA—The Egyptian Syrup & Production Co. recently organized has plans under way for the erection of a new sugar mill, with daily output of about 400 tons of cane sugar to be used for the manufacture of cane sirup and kindred products. The plant is estimated to cost about \$150,000 with equipment. Larkin & Pratt, Arcade Bldg., St. Louis, Mo., are architects. J. N. Nicolay heads the company.

TAMPA—The Southern Bottle Mfg. Co., recently organized with a capital of \$1,500,000, has awarded a contract to the Oatley-Jones Co., Tampa, for the erection of its proposed new plant at Gary, near Tampa. It will be 1-story, 60 x 150 ft., and will be equipped for daily capacity of about 150 gross of milk bottles, jelly glasses, etc. An adjoining building, 36 x 62 ft., will also be constructed. I. F. Jones is president.

KENDAL—The A. B. Hurst Co., recently organized, is arranging for the establishment of a local plant for the manufacture of starch products. It is proposed to develop a capacity of about 3,000 lb. per day. J. B. Hurst is secretary, and W. T. Tomlinson, vice-president and engineer.

Georgia

ATLANTA—The Simmons Plating Works, manufacturer of plated metal products, is planning for the erection of a 2-story addition to its plant for nickel plating and other operations. New machinery will be installed.

Illinois

CHICAGO—Work has been completed on the new gas plant of the People's Gas Light & Coke Co., 122 South Michigan Boulevard, said to represent an investment in excess of \$15,000,000. The plant is constructed in two sections, providing for the production both of coal and water gas. The first noted has a capacity of 14,000,000

cu.ft. per day, and the latter section 26,000,000 cu.ft. daily. The plant will be placed in operation at once.

Kentucky

LEXINGTON—The Great Southern Refining Co. has taken over an oil refinery at Pryse (Estill County), Ky., and will operate the plant in connection with its Lexington refinery. The combined output will total about 4,000 bbl. per day. W. B. Hasset is president, and Paul Blazer, vice-president.

Maryland

BALTIMORE—The Virginia-Carolina Chemical Co., 11 South 12th St., Richmond, Va., has plans under way for the erection of its proposed new fertilizer manufacturing plant at Baltimore, to be 200 x 500 ft., and estimated to cost in excess of \$3,000,000, including machinery. It is planned to commence erection early in the coming year. S. D. Grenshaw is secretary.

Massachusetts

SALEM—The Peerless Leather Co. has acquired the local plant of the Broadley Co., and will establish a new tannery. It is proposed to commence operations at an early date. Machinery will be installed at once.

Michigan

CHASSELL—The Michigan Humus & Chemical Co., has been reorganized as the National Humus & Chemical Co., with capital of \$1,000,000. The company is planning to increase its operations for the manufacture of fertilizer and powdered fuel, and a local works will be established for this purpose. C. F. Hancock is president.

Mississippi

MERIDEN—The Bang-Go Soap Mfg. Co., 2304 Front St., recently organized, is planning for the erection of a new local plant for the manufacture of soap products. R. E. Yarbrough is president, and L. L. Gunn, general manager.

Missouri

KANSAS CITY—The American Gasoline Corp. has work under way for extensions and improvements in the local refinery of the North American Refining Co., known as the Sheffield plant, recently acquired. New process stills and other equipment will be installed, and it is expected to have the works ready for service before the first of the year. The refinery will have a capacity of 4,000 bbl. of oil per day, with lubricating oil works to have an output of 300 bbl. daily.

New Jersey

TRENTON—The Acme Sanitary Pottery Co., May St., manufacturer of sanitary earthenware, has awarded a contract to Solan & Dotter, Inc., for the erection of a 2-story, brick addition, 30 x 128 ft., with new 1-story building adjoining, 18 x 60 ft.

TRENTON—The New Jersey Porcelain Co., Pennsylvania Ave. and Mulberry St., has filed plans for the erection of a new 3-story brick building at its plant.

MILLINGTON—The Asbestos Material Corp. has acquired the plant of the Bateman Co., on Central Ave., heretofore devoted to the manufacture of agricultural implements, for a new plant for the manufacture of asbestos products. The building is 2-story, concrete; possession will be taken at once and necessary equipment installed. It is said that employment will be given to about 70 persons for initial operations.

New York

EAST HAMBURG—Fire Oct. 26 destroyed the plant of the Electro-Refractory Co., Townline Road, manufacturer of steel crucibles, etc., with loss estimated at about \$200,000, of which about \$50,000 represents machinery. Headquarters of the company are at Ellicott Sq., Buffalo, N. Y.

SPARKILL—The Standard Oil Co., 26 Broadway, New York, has taken title to a tract of property totaling about 1,500 acres, in the vicinity of Sparkill and Palisade, N. Y., for a consideration stated at \$2,000,000, and is reported to be planning to use the site for a new oil works.

Ohio

WEST PARK—A. & S. Paint & Varnish Co., Elmwood Ave., has awarded a contract to the George A. Rutherford Co., 2729 Prospect Ave., for the erection of a new 3-story and basement plant, 50 x 70 ft., on Elmwood Ave., estimated to cost about \$45,000. Work will be placed under way at once. A. J. Ferbert is manager.

NEWTON FALLS—The Hubbell Tire & Rubber Co., 6515 Carnegie Ave., Cleveland, has acquired the plant of the Trumbull Tire & Rubber Co., Newton Falls, and will use the property for a branch plant. Machinery will be installed at once and production inaugurated at an early date.

EAST PALESTINE—The National Fireproofing Co., Fulton Bldg., Pittsburgh, Pa. has plans under way for the rebuilding of its plant at East Palestine, to replace the portion destroyed by fire. It will be 1-story, 100 x 100 ft., and is estimated to cost about \$60,000. Sidney F. Heckert, Bessemer Bldg., Pittsburgh, is architect.

Oregon

PORTLAND—The Oregon Brass Works, North Second St., has awarded a contract to Camp & DuPuy, East Adler St., for the erection of a new 1-story foundry addition.

Pennsylvania

PHILADELPHIA—The Pennsylvania Sugar Co., North Penn St., has added to its recent property purchases in the vicinity of its plant on North Delaware Ave., and has acquired the factory of the American Preserve Co., 946-54 North Delaware Ave., 72 x 105 ft., for a consideration said to be \$55,000. The property will be used for expansion.

Texas

WACO—The Waco Refining Co. is planning for the construction of additions to its plant for increased production. The refinery is located in the East Waco district, and was acquired recently by W. A. Rogers and associates. Mr. Rogers is president.

MEXIA—Following the acquisition of an extensive interest in the Humphreys-Mexia Co. and the Humphreys-Texas Co. by the Pure Oil Co., 74 Broadway, New York, said to involve a consideration of \$7,000,000, plans are being prepared for extensions in the properties. A new central oil-collecting and distributing plant will be constructed near Galveston, Tex., with new 130-mile pipeline, estimated to cost about \$3,500,000. A site will be selected at a Gulf Coast point at an early date for the erection of a new oil refinery to cost in excess of \$1,000,000.

Virginia

ALEXANDRIA—Fire Oct. 24 destroyed the plant of the Belle Pre Glass Co., in the northwestern section of the city, with loss estimated at about \$50,000. It is said that the plant will be rebuilt.

Washington

SPOKANE—The Consolidated Diamond Oil Refining Co. has acquired property at Dishman, near Spokane, and contemplates the construction of a new refinery on the site.

Capital Increases, Etc.

THE MARINETTE & MENOMINEE PAPER Co., Marinette, Wis., has disposed of a bond issue of \$2,000,000, to be used for financing general operations, etc.

THE DEGRASSE PAPER Co., Pyrites, N. Y., has filed notice of increase in capital from \$1,000,000 to \$4,000,000.

THE NEW ENGLAND TIRE & RUBBER Co., Holyoke, Mass., has filed notice of increase in capital from \$3,000,000 to \$53,000,000.

THE MAY FOUNDRY Co., Sixty-first and Eastwick Sts., Philadelphia, Pa., has filed notice of increase in capital from \$565,000 to \$10,500,000.

THE CENTRAL STEEL Co., Masillon, Ohio, has arranged for a bond issue to total \$5,000,000.

THE MARDEN, ORTH & HASTINGS Co., Boston, Mass., operating under a receivership since April last, has been acquired by Hunnell & Co., Inc., a new organization, composed of former employees of the company. Offices will be established at 310 Congress St., and operations conducted in the line of chemicals, tanning materials, oils, etc., as heretofore. L. C. Hunnell is president, and G. Warren Heath, treasurer.

THE TUSKELOID Co., 114 East 16th St., New York, manufacturer of composition specialties, has filed notice of increase in capital from \$50,000 to \$100,000.

New Companies

THE DIAMOND SOAP Co., Wilmington, Del., has been incorporated under Delaware laws with capital of \$200,000, to manufacture soaps and kindred products. The company is represented by Artemus Smith, Ford Bldg., Wilmington.

THE DETROIT SAND LIME BRICK Co., 507 Vinton Bldg., Detroit, Mich., has been incorporated with a capital of \$350,000, to manufacture bricks and other sand-lime products. The company has plans under way for the erection of a new local plant. The incorporators are F. William Niemann, Reinhold Polte and Albert H. Meinke.

THE WEYMOUTH CUT GLASS Co., Hammononton, N. J., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture glass products. The incorporators are David Ford, John F. Rithfus and Charles H. Strunk, Hammononton.

THE PENNSYLVANIA LEAD & ZINC Co., Allentown, Pa., has been incorporated under Delaware laws with a capital of \$1,500,000, to operate zinc, lead and other similar mining properties. The incorporators are Horace B. Hemingway and George N. Schaffer, Allentown; and Philip R. Berg, Catasauqua, Pa. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE GENERAL PACKING & RUBBER Co., INC., 28 South Charles St., Baltimore, Md., has been incorporated with a capital of \$10,000, to manufacture rubber products of various kinds. The incorporators are Zachary R. Lewis, Eben J. D. Cross and E. Ridgely Simpson.

THE HERCULENE OIL & REFINING CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are J. M. Shellabarger, J. J. Donovan and E. A. Walsh. The company is represented by Shellabarger & Donovan, 30 Church St., New York.

THE NATIONAL WOODSTAINING CORP., Elizabeth, N. J., has been incorporated with a capital of \$50,000, to manufacture stains, paint specialties, etc. The incorporators are George Seeber, Carl F. Guntrum and Wilhelm Koch, 1191 East Grand St., Elizabeth.

THE EDCO OIL Co., Philadelphia, Pa., is being organized by E. M. and Edward J. Cook, and Daniel A. McKendry, to manufacture petroleum products, lubricating oils, etc. Application for a state charter will be made on Nov. 14. The company is represented by Johnson & Gilkyson, 1211 Chestnut St., Philadelphia.

THE STAINLESS PRODUCTS CORP., Watervliet, N. Y., has been incorporated with a capital of \$20,000, to manufacture metal alloys of various kinds. The incorporators are R. P. and Z. M. Devries, and J. Cran. The company is represented by C. Friend, attorney, Albany, N. Y.

HIRD & CONNOR, INC., Boston, Mass., has been incorporated with a capital of \$30,000, to manufacture chemical products. Frederic C. Van Norman is president; and M. T. Cronin, Medford, Mass., is treasurer.

THE WOODSTOWN PRESS BRICK Co., Woodstown, N. J., has been incorporated with a capital of \$150,000, to manufacture brick, tile and other ceramic products. The company is represented by the N. J. Corporation Guarantee & Trust Co., 419 Market St., Camden, N. J.

THE HANS HINRICHS CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of \$75,000, to manufacture chemicals and chemical byproducts. The incorporators are R. B. Bradley, W. F. Eising and W. J. Rose, 27 William St.

THE SERVUS RUBBER Co., 38 South Dearborn St., Chicago, Ill., has been incorporated with a capital of \$500,000, to manufacture rubber products. The incorporators are Hasbrouck Haynes, Cornelius Lynde and Howard W. Lewis.

THE CORODIUM STEAM PRESSED BRICK Co., Pontiac, Mich., has been incorporated with a capital of \$100,000, to manufacture brick, tile and other burned clay products. The incorporators are Cassius J. Crawford and Roy C. Jenne, Pontiac; and Leon F. Owen, Sylvan Lake, Mich.

THE GOTHAM ASBESTOS & MINERALS Co., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture asbestos products and affiliated specialties. The incorporators are M. L. Hamburger, E. Goodman and J. J. Lazaroe, 25 West 42d St.

THE OSANTOS CHEMICAL Co., 110 South Dearborn St., Chicago, Ill., has been incorporated with a capital of 400 shares of stock, no par value, to manufacture chem-

icals and chemical byproducts. The incorporators are F. W. Metz, A. M. Domber and Guy H. Powell.

THE UNION HILL MIRROR & GLASS WORKS, INC., Union Hill, N. J., has been incorporated with a capital of \$50,000, to manufacture glass products. The incorporators are Samuel Gross, Andrew Darion and Paul Doppler, 404 Main St., Union Hill.

THE CONNECTICUT HARD RUBBER Co., New Haven, Conn., has been incorporated with a capital of \$10,000, to manufacture rubber products. The incorporators are A. A. Smith, J. A. Moffitt and William Baxter, 71 Sea St., New Haven.

THE CONSUMERS' OIL & GREASE Co., Reno, Pa., has been incorporated under Delaware laws, with a capital of \$100,000, to manufacture oils, greases and kindred products. The incorporators are Forest A. Huff, W. W. Turner and W. M. Huff, Reno. The company is represented by the Corporation Service Co., Wilmington, Del.

THE K. B. OIL CORP., Buffalo, N. Y., has been incorporated with a capital of \$300,000, to manufacture oil products. The incorporators are J. H. Tiedemann, and J. A. Clausen. The company is represented by C. D. Coyle, 168 Franklin St., Buffalo.

THE RIVER FOUNDRY Co., Detroit, Mich., has been incorporated with a capital of \$5,000, to manufacture steel and alloy castings. The incorporators are Robert Bahe-man and Joseph C. Arnold, 341 Kitchener St., Detroit.

THE STORM WATERPROOFING CORP., New York, N. Y., has been incorporated under Delaware laws with capital of \$200,000, to manufacture paints and waterproofing compounds. The incorporators are A. K. Dohrman, Eugene E. and Charles R. Allison, New York. The company is represented by the Capital Trust Co., Dover, Del.

THE RED SEAL REFINING Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to manufacture refined petroleum products. The incorporators are H. L. Hagerman, O. A. Burchard and D. S. Fridner. The company is represented by I. W. Bull, 817 Central Bldg., Los Angeles.

THE BOND CHEMICAL PRODUCTS CORP., Wilmington, Del., has been incorporated under state laws, with capital of \$100,000, to manufacture chemicals and chemical byproducts. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

Industrial Notes

THE AUSTIN MACHINERY CORP. announces that the Canadian Austin Machinery Co., Ltd., Woodstock, Ont., incorporated under the laws of Canada, will henceforth act as sole manufacturer and distributor in Canada of the complete Austin line of earthmoving and concrete machine equipment. The manufacture of Austin machinery at Woodstock enables the Canadian company to supply economically its line of equipment and furnish service in maintenance.

WURSTER & SANGER, chemical engineers, announce the opening of offices at 5201 Kenwood Ave., Chicago, where they will be engaged in both consulting and construction work relating to the manufacture of soap, fatty acid distillation plants and glycerine plant equipment. Oscar H. Wurster has had long experience in plants of this sort, having been employed by M. Work Co., Lever Bros. Ltd., Morris & Co., packers, and the Louisville Soap Co. Walter E. Sanger was formerly chemical engineer with Swift & Co., packers, and the Procter & Gamble Soap Co.

L. O. KOVEN & BRO., Jersey City, celebrated its fortieth anniversary Sept. 28. A dinner was given at the company's cafeteria. The entire office force and a few outside friends were present. A number of interesting speeches on the history of the company were delivered.

L. C. BIGLOW & Co., INC., 232 West 55th St., New York City, has been appointed New York district agent for the Hartford Tap & Gauge Co., the Hanson-Whitney Machine Co., Inc., the Taylor & Fenn Co. and the Whitney Mfg. Co., all of Hartford, Conn.

BRITISH FURNACES, LTD., Millbank House, 2 Wood St., London, S. W. 1, England, with an authorized capital of £25,000 was organized during the early part of July, this year, for the purpose of manufacturing and selling Surface Combustion apparatus in the British Empire. The principal stockholders consist of the Bryan-Donkins Co., Ltd., machinist and founder, Chesterfield, England; Woodall, Duckham & Jones, Ltd., engineer and manufacturer, London, England, and the Surface Combustion Co., Inc., Bronx, New York, owner of the surface

combustion patents and manufacturer of industrial furnaces. The Surface Combustion Co., Inc., is now represented in all the principal European countries and many large industrial furnace installations have already been made. The Compagnie Générale de Construction de Fours, Paris, France, is the sole licensee and manufacturer for Surface Combustion patented apparatus in France and its colonies, Belgium, Holland, Switzerland, Italy, Spain and Portugal. John H. Bartlett, Jr., foreign representative for the Surface Combustion Co., Inc., of New York, has had charge of this work during the last few years and personally supervised the organizing of the foreign sales and manufacturing departments for the companies which took over the Surface Combustion Co. rights.

THE AMERICAN BOSCH MAGNETO CORP. has recently appointed new managers in its New York and Detroit branches. George Shortmeier, formerly New York manager for the Madison Rubber Co. and later district manager at New York for the Sinclair Oil Co., has been placed in charge of the Bosch branch at New York, replacing O. S. Stanley. Charles L. Shedd is now manager of the Bosch branch at Detroit, taking the place of Roy Davey, who has been made manager of the manufacturing sales department at Springfield, Mass. Mr. Shedd was at one time promotion manager of the truck division of the Packard Motor Car Co. at Detroit, subsequently served as official distributor at Omaha for that company and still more recently acted as sales manager of the Republic Truck Corp. at New York City.

THE BLAW-KNOX Co., Pittsburgh, Pa., announces the addition of H. O. Davidson to its staff. Mr. Davidson will have entire charge of the Prudential Sectional Building Department and will also be general manager of the C. D. Pruden plant of the Blaw-Knox Co. at Baltimore, Md. Mr. Davidson was connected for eight years with the Hydraulic Steelcraft Co., being general manager of that organization at the time he severed his connections to become a member of the Blaw-Knox staff.

JOHN F. ABERNETHY have moved to new offices and shops at 708-10 Myrtle Ave., Brooklyn, N. Y.

C. H. BOLEY & Co., INC., manufacturing industrial chemist of Philadelphia, Pa., announces the addition on Sept. 1 of T. Perry Rider, as sales manager. Mr. Rider was for many years connected with Schofield, Mason & Co., Philadelphia, Pa.

EDWARD O. BENJAMIN recently moved his offices to 530 Park Row Bldg., New York, continuing the practice of consultation, research and testing of apparatus and material relating to electrochemical welding, industrial gases, oil, rubber and allied industries.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN IRON AND STEEL INSTITUTE will hold its twentieth general meeting at the Hotel Commodore, New York City, on Friday, Nov. 18.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society regular meeting.

Armistice Day And a New Epoch

DULL indeed must be the mind and unsympathetic the soul that could remain unmoved by the impressive ceremonies in Washington and Arlington last Friday when America honored her nameless dead in the Great War. In the presence of a notable company representing the world's principal nations our own Unknown Warrior was honored with tributes that nations only can bestow.

The incident is rich in lessons that are not far to seek. They comprehend the obvious duties of those who are left to win the fruits of peace. We may not share the glory of this unknown soldier who fell on the field of battle, but we can and must accept the challenge of his sacrifice by doing the world's work better than it was ever done before. His death is also a challenge to the world's statesmen who are gathered in Washington to find ways of promoting peace among the nations; and in the sincerity of their participation in the memorial exercises we may find hope for the practical solution of the problem. Indeed the opening of the conference on disarmament was most auspicious, and is a fine augury for future international relations that will make unnecessary such sacrifices as our Unknown Warrior was called upon to make.

Armistice Day, 1921, was no ordinary holiday. No such auspicious conjunction of events has ever been known before. We believe it will mark the opening of an epoch of good will and friendship among nations and a period of prosperity and human happiness unparalleled in the history of the world.

Agricultural Support For the Chemical Industry

AT THE recent meeting of the Association of Official Agricultural Chemists a very significant resolution was adopted. It reads:

Whereas, the research necessary for the solution of agricultural and other industrial problems can only be carried on with the aid of a firmly established chemical industry; and

Whereas the development of chemical industry is one of the great factors tending toward the future welfare of our country, whether in times of peace or in times of war; it is therefore

Resolved, That the Congress of the United States is hereby urged to continue adequate, beneficial legislation until the various chemical industries in the United States have become firmly established.

In the first paragraph, the reference to "agricultural and other industrial problems" emphasizes a fact which agricultural interests usually do not realize—that agriculture really is an industry. Furthermore this paragraph recognizes the close relationship of agricultural problems and chemical industry.

The tendency which our national legislators have recently exhibited of grouping themselves in various

ways according to the nature of their constituency is in striking contrast to the tendency among the industries and the branches of technology. There is constantly increasing an appreciation of the mutual interests of the industries. We are coming more and more to realize that all industry demands the mining of coal, the movement of freight, the smelting of metals and the cutting of lumber on a basis of fair dealing both for the wage earners involved and for those who supply the invested capital. No one of our major industries can break down without immediately producing suffering to a greater or less degree among all others. It is a great mistake, therefore, to think of legislation intended to foster the interests of a single trade or class.

In no line of science or technology is this fact brought out more strongly than in the field of chemical industry. One man's final product is the next man's raw material. Unless the movement from natural resource to final commodity can go forward step by step with profit to each participant who really contributes to the industrial movement, we cannot expect most economical and satisfactory service to the final user. Co-operation of agricultural with manufacturing interests and manufacturing with transportation agencies can produce the best result. It will be well that every group recognize this fact and preach in support of the text which the agricultural chemists have so properly emphasized.

A Survey Of Special Libraries

THAT the special library is a valuable business asset has long been recognized by the engineering profession. Many of our industries too have come to realize that business policies are based most profitably on an accurate knowledge of facts, especially the sort of facts that are available in the technical books and current literature of the industry.

An idea of the extent to which American business is relying on its special libraries can be gained from the report of a survey recently completed by the Special Libraries Association and to which reference is made on page 909 of this issue. Of 1,300 special libraries included in this survey, 95 were collections of specialized information on industry and manufacturing, 66 were engineering libraries, 32 were chemical, 11 were mining and many of the remainder gave considerable attention to these subjects. It is interesting to note that three other classes—namely, business, banking and finance—showed a total of 142 sources of special information. Perhaps as the control of our larger industries is gradually passing into the hands of the banker and capitalist, these men are beginning to feel the need for scientific and technical knowledge. If these men are to guide our industries, it is obvious that they must be-

come to some degree familiar with their technology in order to be able to look beyond balance sheets to plant processes, yields, equipment, and research. Other financiers, who are less directly connected with industry, are called on to furnish advice on investments, and to do this intelligently they should have a readily available source of technical information.

The important rôle of the library in the program for the elimination of industrial waste has recently been brought to our attention by K. C. WALKER of the Bureau of Mines at Pittsburgh. His letter, which we are glad to print on another page of this issue, shows clearly that the special library is an important element in saving or preventing waste in our industrial world.

There are many other ways in which the special library demonstrates its value to industry. Not long ago one of our contemporaries cited an instance of a Western steel company that spent \$10,000 on a special research problem. When the librarian of the company heard of the result, he sent a book from his shelves to the president, referring him to a complete solution of the problem which had appeared several years before in a well-known technical book. Such an occurrence is unusual, to be sure, but it serves to emphasize the importance of utilizing the experience of others and beginning research with a survey of existing knowledge.

HERBERT HOOVER has aptly stated the *raison d'être* of the special library in the following words: "The function of the business library, as I understand it, is to collect and to preserve data of value to the business executives and so to organize this information that it will be available for use with a minimum of delay. There can be no question of the value of such service to the larger business firms when the work is properly organized and the librarian in charge has a clear conception of the possibilities of his position. The librarian who can make his service an integral part of his firm's organization may become a positive factor, both in the increase of profit and in the development of constructive business standards."

Deterrents for

Methanol Consumption

HEADLINES in daily newspapers continue to announce deaths or blindness resulting from the error of drinking some decoction said to be whisky. Each account lays the blame to "wood alconol" (not methanol, mark you, plain "wood alcohol"). A recent meeting of the Pennsylvania Medical Society spent a day listening to addresses on the diagnosis and treatment of methanol poisoning and to information on the number of cases which occur. In view of the very great amount of human damage being done, the physicians decided upon steps to educate the general public on the poisonous qualities of relatively small amounts of methanol, so that eventually a law could be passed absolutely forbidding its manufacture. Meantime they demanded that any package or substance containing methanol be marked "Poison" conspicuously, and a special revenue tax be assessed to bring the price up to and beyond that of denatured industrial alcohol.

Now all chemists will readily admit that doctors of medicine do not know a great deal about chemistry and the chemical industry, and what they do know is largely wrong. Otherwise they would know that methanol already costs twice as much as denatured ethyl alcohol, and they would remember that their indispensable formaldehyde all comes by way of methanol.

But that does not alter the fact that doctors have a deal more influence in public affairs than the chemists. In fact, if the medical fraternity were to unite on a movement to ban "wood alcohol," no matter how mistaken such a move would be, it would be a safe bet that the chemists could not save "methanol." Pleas based on the commercial importance of the substance would be as unavailing as was the specter of idle breweries to halt the Volstead act.

Theoretically, the first step toward the prevention of continued methanol poisoning would be to discover whether its source was commercial methanol or industrial alcohol denatured by the other and retailed for "anti-freeze" liquids and such like. But bootleggers are notoriously hard to catch, and once caught, do not divulge many of the tricks of the trade. However, since the trade itself is wholly unscrupulous and one for profit, it is to be presumed that the "kick" which is mixed into their wares is the cheapest alcohol they can get, and no qualms are felt as to whether the stuff is made unfit for human consumption (that is, denatured) by a liquid which is actually a deadly poison, and is so marked on the original container. Let the thirsty buyer beware!

In order to protect this weakling, all alcohol whose point of consumption is doubtful must contain a small amount of some substance which would not unfit the distillate for legitimate industrial uses but which, when diluted to a potable degree, would unmistakably make its presence known by a revolting color, taste or odor. TUNISON has listed a number of denaturants; would not some of the intensely bitter alkaloids do the trick? OUTERBRIDGE has already informed the chemical fraternity of a simple addition (7 mg. fluoresceine per 100 c.c.) which has effectually protected large warehouse stocks of ethyl alcohol from pilferage for many years. Dilution with water to potable proof causes a yellowish green fluorescence, reminding even the most hardened sinner of the hell-fire in store for him if he stomachs it.

Other more effective deterrents may already be known, or doubtless can be found, if those now available are so expensive as to prevent their use. Their action, even their presence, does not need to be widely advertised, and the burden should be on the shoulders of the purchaser to prove that they unfit the alcohol for legitimate use.

A stitch in time saves nine!

The Dunce

And the Devil

SOME day, when we are all settled down in ease and comfort and we feel like it and haven't any pressing obligations to bother us, we plan to write an allegory about the *Dunce* and the *Devil*. The problem is to accomplish the utter ruin of something or somebody good, like *Christian* in "Pilgrim's Progress," in which the *Devil* will be foiled in his wicked wiles because the *Dunce*, in his effort to save the hero, will beat the *Devil* to his own goal.

We have said it before and we repeat it without fear of contradiction, that every one of us is, in one respect or another, feeble-minded. Some of us can't mend a clock, others can't keep accounts, others can't saw a board straight or play poker or golf or sell goods or write poetry or sense relativity or do any one or more of thousands of things that many men do well. So, in respect to his inhibitions, each of us is a dunce. Apart from these inhibitions we may be men of signal in-

telligence. Like the genius, the dunce is a specialist in his line; but unlike the genius, he is usually unaware of this fact. You don't have to look like a dunce, or even to act like one, to be one.

The other day we heard of a man who made a remarkable success with his department store. He knew how to sell smocks and frocks and gowns and yarns and needles and pins and bonnets and laces and fur coats and silk stockings and all sorts of things to women. He knew how to advertise, when to have bargain sales, when to mark up and when to mark down; in short he was so successful a merchant that he retired in affluence when a comparatively young man. He tried the rest cure in California, but he was a little young for the long sleep and it got on his nerves; so he returned to the home town to be a bank director and a leading citizen.

Under the auspices of a leading firm of dealers in securities there took place a consolidation of a number of manufacturing concerns making paper. Local subscribers took a large block of the new stock and bonds and the bankers saw to it that some effective window-dressing was done in the personnel of the new organization. The returned Leading Citizen was made vice-president in charge of sales, and since every local stockholder and bondholder and his wife had bought things from him, all knew him to be a great merchant who was a master of sales. Everything went well until the slump in the market came along, and then the troubles began. He did not know the uses of paper or who made this or who bought that or how to hustle out and grab what was left of a market or how to get people to use his company's products as measures of economy or advantage—in short, he was lost in his job. Old Uncle Bankruptcy used to croon his doleful song into his wakeful ear by night and the affable lawyer who was a friend of the judge and likely to be appointed receiver if things should go wrong began to make friendly calls by day to "get the hang of the business." Those were gloomy times!

Now the Leading Citizen was incompetent as a paper salesman, but otherwise he was a man of rare judgment and ability. He saw that they must sell their product and that he was not succeeding as well as others who knew the business. So he resigned and they called in a competent and informed man who took his place and saved the concern. The Leading Citizen was a man of character, because he did not let his own vanity stand in the way of saving the investments of his neighbors. There are not very many men who reach this modest height. The experience aged him so that he can now enjoy the climate and the quiet and calm among the other wuzzers under the orange trees along the Pacific shores. He set an excellent example.

An Old Fake Persists

"I love it, I love it, and who shall dare
To chide me for loving that old arm-chair?"
But closer and dearer by far is the name
Of the man that can teach me to beat any game!

THIS desire to beat any game is truly a blind passion. We want to get rich quick with such intensity that we haven't even the patience to listen to the voice of reason or of experience that tells us when the cards are stacked against us.

On February 2 last we published an article on "Easy Money From Peat"; and "CHARLIE," the assistant and secretary of the corporation, wrote to us after reading

the article that we had been correct in our diagnosis of the thing as a fraud; that he had lately discovered the fact that the gasoline and methanol had been put into their respective containers before "the professor" had charged his retort with peat or begun to "make" the gasoline. CHARLIE wrote to us that he had resigned on discovering this fact, and we published his letter in our March 23 issue.

On May 24 LOUIS ENRIGHT, "the professor," was arrested for practicing fraud, and was released on \$1,000 bail. He is still at large.

On June 8 we published another letter advising us that we had saved, by our exposure, the funds of a number of prospective investors.

Later the New York *World* published in one of its editions a record of "Gasoline From Peat," setting forth ENRIGHT as a gifted inventor and, from reading the article, it appeared as though he were offering a pretty good thing. We sent a reprint of "Easy Money From Peat" to the editor of the New York *World*, but received no reply. We have failed to observe a retraction of the misleading article, but it may have appeared. Now comes the *Evening Telegram* of September 23, which tells us that LOUIS ENRIGHT, the seventy-nine-year-old president of the Enricht Gasoline Corporation, has been "demonstrating" again, this time at Seaford, L. I. It was the same old game of putting peat into the same apparatus that we depicted in our report; the peat body was "ignited and reduced to vapor," then forced through a "condenser," which transmogrified some of the gas into methanol, then through a "compressor" and past a catalyzer, etc., until presto! there was the gasoline! We told all about it, even to how the gasoline leaked out of the back end of the apparatus before the peat was put into the front end, and how the whole thing was a palpable fraud. Did it make any impression? Not beyond our own circle of readers, apparently. Here is the final paragraph of the news item in the *Evening Telegram*: "There were twenty-five or more present when the peat in the retort was ignited and the fire started to blow the gas through the apparatus. [In the earlier demonstration this was accomplished by ENRIGHT's remarkable pump.] As far as any one of the observers could tell the thing worked flawlessly, for in a few moments gasoline began flowing from the cooling coil into a barrel, and bottles were filled for the spectators."

What was the matter with the eyes of those twenty-five or more observers? Were they all so credulous that when they saw gasoline coming out of a spigot they were convinced it had just been made? In the former demonstration which we reported a witness requested the old boy to repeat the operation after his gasoline tank had been displayed and the contents removed. He showed hot indignation that anyone should lack confidence in him. But of course he refused. Now we advise our neighbor the *Evening Telegram* that it has been advertising in its news columns a rank fraud; that ENRIGHT has a bad record, and has been in this and similar games for years; that if the reporter had opened up the apparatus he would have found all the gasoline and methanol that came out safely stored there before the operation began, and that the sole beneficiary of money invested in ENRIGHT's scheme is ENRIGHT himself, and not the investor.

Will the *Evening Telegram* tell these facts to its readers for their benefit? It should. But will it?

Readers' Views and Comments

Regarding Solvent Recovery Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—Our attention has been drawn to a letter signed by James C. Lawrence entitled "Recovery of Volatile Solvents by the Bregeat Process" and published on page 93 of your issue of July 20, 1921. In this he speaks of "my own firm of Blair, Campbell & McLean, Ltd., Glasgow, Scotland." We desire to inform you that Mr. Lawrence is not a member of the firm of Blair, Campbell & McLean, Ltd., has no connection with it and is not authorized to use the name of that firm for any purpose. We desire further to inform you that although the American Chemical & Sugar Machinery Co., which Mr. Lawrence refers to as "the American offshoot of Blair, Campbell & McLean, Ltd.," was authorized for a time to act as the American agent of Blair, Campbell & McLean, Ltd., it now has no connection whatever with the latter firm.

Glasgow, Scotland. BLAIR, CAMPBELL & MCLEAN, LTD.

To the Editor of Chemical & Metallurgical Engineering

SIR:—With reference to the communication from Blair, Campbell & McLean, Ltd., of Glasgow, Scotland, I would advise that the holdings of that company in the American Chemical & Sugar Machinery Co., of Philadelphia, have been acquired by the undersigned, and that the latter firm continues to manufacture its full line of equipment in its new works at Chester, Pa., now unhampered by territorial or agency agreements with Blair, Campbell & McLean, Ltd., of any nature.

Chester, Pa.

JAMES C. LAWRENCE.

Rôle of Libraries in Elimination of Waste

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was greatly impressed by the array of special articles appearing in your issue of Aug. 31, 1921. It would seem as though every corner of our industrial house had been searched for ways and means of preventing waste, but no person seems to have written anything on one important phase of the waste question. I refer to the very important part the so-called special library plays in the elimination of waste.

In the first place, what does a special library do for an industrial organization? It acts as a clearing house of printed information for the field in which the organization is at work. We know what the ordinary banking clearing house has done for the banks of this country. It has opened the way for a quicker dispatch of the banks' business and thereby eliminated the *waste motion* incident to the old methods of banking.

The special library when properly supported and efficiently managed will accomplish savings throughout the entire fabric of any organization.

Andrew Carnegie has been often quoted as saying that his organization had wasted thousands of dollars by failing to find out what others had done along the same line before they experimented. Obviously it is cheaper to send experts to the library and spend a few days searching for records on a given subject than to go ahead blindly building expensive apparatus, employing many men and consuming expensive material only

in the end to find the experiment a failure, the same as others before you. One large concern is known to have spent in the neighborhood of \$50,000 on an experiment which resulted in failure. Yet records were available in the local public library showing that the experiment had been tried by someone else and failed.

Saving is preventing waste. If we can find ways and means for saving steps in an operation we are preventing the execution of wasteful operations. One chemist in a large Ohio manufacturing concern lost a train while in a large industrial city. In order that he might utilize the intervening time to best advantage he found the public library of that town and spent his time browsing about. The result of his browsing was the discovery of a process that had been tried elsewhere which saved his concern \$300 in one operation.

Still another metallurgical concern that I know of was about to start an expensive experiment, but just before launching the experiment one of the workers saw some information in print, brought to his attention through the library, that led to the subsequent abandoning of the experiment with much saving.

Instances of this nature might be multiplied. There is no need of enlarging upon the saving effected by properly supported special libraries manned by trained workers. The trouble is that most industrialists who have tried to experiment with libraries have assigned the task of organizing and operating to stenographers and similar people totally unqualified.

The special library is the one important element in our industrial world that can save or prevent waste. When run efficiently it prevents waste before it can begin by focusing all the known information on a task or project.

Research Reference Assistant,
Bureau of Mines Experiment Station,
Pittsburgh, Pa.

De-gasifying Silver With Iron Block

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 457 of your Sept. 7 issue occurs the following sentence: "The practice of inserting a piece of iron into the metal bath of this furnace (the Ajax-Northrup High Frequency) would materially disturb the induction."

This remark is in an article on Electric Furnaces, by J. Herlenius. The matter of placing iron in electric furnaces for the purpose of absorbing gases is touched upon in an editorial article in the same issue, page 450. In view of the prominence that you have given the matter, we think it proper to forward a statement which proves the incorrectness of the sentence quoted above. We wrote to Mr. Herlenius about it and he replied in part as follows:

"I regret the mistake made as referred to in your letter, but I took for granted that the iron would undoubtedly, on account of its lower electrical conductivity, materially disturb the induction. However, I appreciate the fact brought forth in your letter that the lines of force are absorbed by the graphite crucible."

We were certain of the truth of our contention, but wished to make, and then explain, a simple experiment which would make the facts clear to your readers.

Accordingly we placed a conducting graphite crucible in a large inductor coil, and then placed in the otherwise empty crucible a small can made of sheet iron. The crucible heated rapidly and attained a red heat within 15 or 20 minutes. The can, however, heated no faster than it would have heated simply by radiation from the walls of the crucible. It was possible to pick up the can with the fingers after the crucible was approaching red heat. Afterward the crucible was removed from the inductor coil and the can alone was placed centrally in the coil upon a stick of wood. When the high-frequency current was turned on the can became red hot almost immediately.

This experiment verifies the conclusions of theory that there are no free "lines of force" inside of the graphite crucible (provided this has good electrical conductivity and the wall is not too thin), and that therefore iron within the crucible would have no possible effect upon the induction.

E. F. NORTHRUP.

Trenton, N. J.

Vice-President and Technical Adviser
Ajax Electrothermic Corporation.

Hardened Rosin and Resin Esters

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the writer's article on "Hardened Rosin and Resin Esters," in your issue of Sept. 7, the statement was made on page 474 that "Gardner ('Papers on Paint and Varnish,' p. 234) used 55 lb. of glycerine to 100 lb. of rosin. . . ."

Referring to this, Dr. Gardner has advised me that the figure 55 in his book is a misprint, and should read 15 lb. He says further: "We have never used more than 25 per cent in our experiments, and have found that 12 to 15 per cent is sufficient, although more is frequently used in practice."

A. MURRAY.

Springfield, Mass.

Variation of Hardness in Quenched Specimens

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 695 of the Oct. 12 issue of CHEMICAL & METALLURGICAL ENGINEERING an article by Carle R. Hayward seems to imply that the center of a heat-treated steel bar is necessarily harder than the edge. It is rather unfortunate that the conditions surrounding his experiments were such as to bring about this result, as the reverse effect is equally possible.

A paper by Honda, Matsushita and Idei presented at the May meeting of the Iron and Steel Institute, "On the Cause of Quenching Cracks," gives sufficient data to show that both effects are possible and outlines the conditions necessary for either result. These investigators conclude that:

(1) In a soft quenching, such as in oil from a temperature not exceeding 820 deg. C., the hardness of different specimens is greatest in the outer portion, and decreases from its periphery toward the center.

(2) In a medium quenching, such as that of a steel 0.9 per cent carbon at 780 deg. in water, or that of steel 1.47 per cent carbon at 900 deg. in oil, hardness is nearly constant everywhere.

(3) In a hard quenching, such as that of a steel containing more than 0.68 per cent carbon from 800 deg. C. or a higher temperature in water, the hardness is least in the outer portion and increases rapidly toward the center.

An examination of Hayward's data shows that all tests fall within group 3, where the hard center may be anticipated. Honda explains the phenomenon by his theory of quenching which assumes that the A₁ transformation is not a single but a compound transforma-

tion consisting of austenite $\rightleftharpoons$ martensite $\rightleftharpoons$ pearlite. In the case of hard quenching where the rate of cooling of the exterior parts through the transformation range is very rapid the last part of the transformation is completely arrested and the first change partly so. The central portions do not cool quite so rapidly and the transformation is nearly all to martensite. It is well known that austenite is softer than martensite. For a soft quenching the cooling in the outer portions is slow enough to permit the formation of martensite but not pearlite, while in the center much pearlite is formed, and for this condition the outside would be the harder.

It is also apparent that the size of specimen which also controls the rate of cooling would have an effect in determining whether the inner or outer portions of a quenched steel bar were the harder.

Physicist, Bureau of Standards.
Washington, D. C.

R. W. WOODWARD.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. Woodward's discussion of my article on "Hardness Variations in Heat-Treated Steel" is just what I hoped for. The data which I presented and more in my files show with scarcely an exception that round steel bars are harder at the center than at the outside. Any evidence to the contrary will be a contribution to our general knowledge of the subject. Unfortunately I have not at hand the paper by Honda, Matsushita and Idei quoted by Dr. Woodward and cannot adequately discuss their results. Their conclusions given in Dr. Woodward's communication refer apparently only to steels in the quenched condition, whereas most of my results were on steels reheated after quenching. Any theory of quenching hardness which involves the presence of austenite in the steel is of limited application, for it is doubtful if austenite is present in appreciable quantity unless a special steel is used or the cross-section rather small and the quenching is sudden. No austenite would be present in ordinary steel reheated after quenching. As noted by Dr. Woodward, the size of the specimen is very important.

CARLE R. HAYWARD.

Mass. Inst. of Technology,
Cambridge, Mass.

Non-Magnetic, Flame-, Acid- and Rust-Resisting Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have seen the article published in CHEMICAL & METALLURGICAL ENGINEERING for Oct. 26, 1921, page 797, on "Non-Magnetic, Flame-, Acid- and Rust-Resisting Steel," and have read the article with much interest.

I regret very much that a misstatement appears in the caption of the article: ". . . but after heat-treatment become hard and resistant to attack of all agencies." As a matter of fact, it requires no heat-treatment whatever to make the steel resistant to attack, and furthermore it is an error to say that it becomes hard after heat-treatment, as whatever hardness this steel has is natural to it. The only case in which we heat-treat the steel is in annealing for cold forming.

I should appreciate it if you would correct this statement that the steel "after heat-treatment becomes hard and resistant." To repeat, it requires no heat-treatment whatever to bring out its resistant qualities.

Crucible Steel Co. of America,
Pittsburgh, Pa.

C. M. JOHNSON,
Director Research Dept.

Eugene Schneider, Fritz Medalist

ASCHNEIDER is nearly as well known as a Big Bertha to the doughboy and American newspaper reader. Schneider, the creator of Schneiders and 75's without number, is also known personally to many fortunate American metallurgists who met him during 1919, when he was with us, the president of the French Economic Mission to the United States. Then many honors were given him, chief among which were the Gold Medal of the Mining and Metallurgical Society of America, honorary membership in the American Iron and Steel Institute, the degree of Doctor of Science by the University of Pittsburgh, of Doctor of Science by Western Reserve University in the city of Cleveland and of Doctor of Engineering by Stevens Institute of Technology.

It was only fitting, therefore, that the American Engineering Societies should send their delegation from England to France to present him their most valued token of esteem, the John Fritz Medal.

Eugène Schneider, ironmaster, owner of the Schneider Works, Member of the Chamber of Deputies from 1898 to 1910, president of the British Iron and Steel Institute, 1918-1920, was born at Le Creusot, France, in 1868. He is the grandson of a Lorrainer Schneider (1805-1875), an ironmaster of Bazeilles, who at the beginning of the last century purchased the former royal foundry of Le Creusot, which was built in 1782 under the patronage of Louis XIV.

Eugène Schneider made an early start in business. In 1887, after finishing his studies and completing his military service, he began work for his father and was soon taken into partnership. In 1898, at the death of Henri Schneider, he became the head of the business and succeeded his father in the Chamber of Deputies.

Before the war the activities of the Schneider Works extended over various branches of the iron and steel industry, including mechanical and electrical engineering and shipbuilding. Moreover, Mr. Schneider had developed the manufacture of munitions—especially artillery—to a high point of perfection, a circumstance which was of tremendous value to France in 1914 when hostilities began.

Since the first, however, his aim has been to improve the institutions which his father founded. Especially has he been active in developing a fine spirit of endeavor and better understanding of the rules of life among his employees and has striven in every way possible to improve their material conditions of living. He

has introduced the most modern safety appliances; he has organized advanced technical classes; extended the pension system inaugurated in 1877 long before national legislation touched this subject, provided medical inspection in the schools, established classes for instruction in domestic economy and made provisions for the care of orphans and of children who have lost one of their parents. The Schneider schools are regarded as models for the preparation of engineers, foremen and workers. Thanks to the encouragement which Mr. Schneider gave to the practice of thrift as well as to the loans he made, the workers in his factories have their own homes and gardens.

Production fell off in the Schneider Works with mobilization, but by the end of 1914, in spite of the shortage in labor and raw material, a tremendous effort was

made to increase the production of steel, the construction of cannon of all calibers, gun carriages, shells, and all other materials necessary for national defense. The German invasion captured 81 per cent of the blast furnaces of France and 63 per cent of its steel-making capacity. Yet within 2½ years the number of blast furnaces was trebled and the number of open hearths had increased 60 per cent. Before the war was ended rifles were being produced at 290 times the former annual rate; machine guns 70-fold, 150-mm. shells 225-fold and 75-mm. shells 15-fold, the latter reaching the enormous number of 200,000 a day.

In all this Schneider's efforts were an important factor. No less than 250,000 men were employed by him at Le Creusot and his other steel works, shipyards, iron and coal mines, optical works, machine tool plants, electrical shops, Die-

EUGENE SCHNEIDER

sel engine works, locomotive works and bridge plants. This single organization supplied three-quarters of all the French artillery, including 21-in. guns, besides one-half the American heavy artillery, all its field guns and many hundreds of cannon to Belgian, Italian, Rumanian, Russian and Serbian armies. This effort spread to the countries of the Allies and particularly to America, where, in March, 1915, Mr. Schneider sent special engineers to introduce French methods of manufacturing steel for shells and cannon. When the official French mission arrived in the United States to purchase steel, it found its task greatly lightened by his work.

After the armistice the efficient organization of the Schneider Works was as rapidly as possible converted from a war basis to a peace footing, and already, in spite of the difficulties of the present-day situation, the construction of locomotives, tractors, turbines and electrical machinery of all sizes and powers has begun.

Importance of the Olefine Gases and Their Derivatives

I—Sources and Uses of Ethylene and Propylene*

A Brief Review of Researches Which Have Formed the Foundation for an Olefine Gas Industry—
Corresponding Alcohols and Artificially Prepared Gas Mixtures as Sources of Olefines—
Properties and Applications of Ethylene and Propylene

By GEORGE O. CURME, JR.

AS THE past two decades have witnessed the rapid rise of a new branch of the organic chemical industry, based on the conversion of acetylene into organic products of commercial importance, so there has also been a somewhat slower but an even more promising movement toward the construction of another new division of the industry through the utilization of the related and widely distributed hydrocarbons, ethylene and propylene.¹ In the case of acetylene, the period beginning with the initial discovery of Kutscheroff in 1881,² leading the way to acetaldehyde and all its derivatives, and that of Berthelot in 1869,³ leading to the large variety of chlorinated products and extending to the commercial development of these basic processes, was relatively short, due in no small part to the epoch-making discovery of Willson⁴ which gave the industrial world a bountiful supply of calcium carbide and pure gaseous acetylene. In the case of ethylene and propylene the start was made much earlier, but until the great war brought into sharp emphasis the vital necessity of large quantities of ethylene, in particular, the commercial development of the olefine gases was held back, and enjoyed only a scattered attention in disjointed applications. It may be truly said that today there is no co-ordinated large-scale industrial development of this field, but from many quarters there are coming signs of activity that indicate a growing realization of its commercial importance.⁵ At the present writing a small plant is already in regular operation under the author's direction, and scattered products are offered on the market by other companies in the United States, and abroad, showing a need for ethylene and propylene products by the modern chemical industry.

EARLY STUDIES OF OLEFINE GASES

As early as 1795 the preparation of pure ethylene from the even earlier known ethyl alcohol was described

A contribution from the Mellon Institute of Industrial Research of the University of Pittsburgh. The writer wishes to acknowledge here his gratefulness to E. R. Weidlein and W. A. Hamor, of the Administration of the Institute, for their co-operative support and encouragement.

*This article, the first of a series of five, treats in a preliminary way of certain general phases of the researches conducted continuously by the writer over a period of seven years, since 1914, in the Mellon Institute of Industrial Research of the University of Pittsburgh. The processes developed now constitute the basis of the industrial operations of the Carbide & Carbon Chemicals Corporation's plant at Clendenin, W. Va.

¹The purpose of this article is to outline in a general way the technical importance of the olefine gases, as demonstrated by the recorded literature and supported by the writer's own work. It is manifestly impossible to recognize in such a brief paper all the valuable contributions made by the many investigators in this field, and accordingly only a few of the most important are cited. The bibliographic citations referred to will supply the reader with the references necessarily here omitted.

by the four Dutch chemists Deimann, Troostwyk, Bondt and Louwrenburgh,⁶ who also prepared the derivative, ethylene dichloride, in pure state at the same time, thus giving the name of olefiant gas (oil-forming) to the ethylene, which later has come to designate the whole series of homologous substances, the olefines. In 1826 Hennell,⁷ working in Faraday's laboratory, produced ethyl hydrogen sulphate from ethylene and sulphuric acid and established its relationship to ethyl alcohol. This same discovery was reannounced by Berthelot in 1855⁸ and was promptly capitalized by the Frenchman Cotellet,⁹ who in 1862 organized a company to produce ethyl alcohol from the then known ethylene content of illuminating gas by absorption in sulphuric acid and subsequent hydrolysis to yield ethyl alcohol. This enterprise was never carried into large-scale operation, and Cotellet's motives were even cast under suspicion by certain of his contemporaries. Nevertheless it is very similar indeed to the proposal which is being discussed seriously today by British chemists and which is being carried out on a large experimental scale.

At only a slightly later date Berthelot¹⁰ announced the absorption of propylene in sulphuric acid, and, by a similar process to the above, the production of isopropyl alcohol. This process, too, lacked support at the time of its discovery, but has been revived without material modification within recent years.

Again in 1900 a German, P. Fritschke,¹¹ came to the United States to take advantage of our then rather unjust excise laws, requiring tax on alcohol used in making ether, and erected a plant in Richmond, Va. This plant operated until 1907, making commercial ether from the ethylene produced in the cracking of petroleum. Since that time the Germans, making use of their cheap potato spirits, developed a process in operation for several years at Bitterfeld for producing ethane gas from ethylene by hydrogenation.¹² This was used as a refrigerant to supplant carbon dioxide on account of its better vapor pressure characteristics. Also a rather extensive production of ethylene chlorhydrin from ethylene and bleaching powder was undertaken by certain of the German and Swiss dye companies for use in an improved indigo synthesis. This later was extended under war-time conditions to the manufacture of "mustard gas" in the German offensive gas warfare, as well as to the production of nitro ethylene glycol for use as a propellant. Also within this same period many

German and other patents have appeared for producing ethylene from acetylene by partial hydrogenation. It has been stated that ethyl alcohol has been made from this ethylene,¹³ although the more recent production of ethyl alcohol from acetylene through the intermediate formation of acetaldehyde has supplanted any efforts along this line.

RECENT DEVELOPMENTS

In this country the Commercial Research Co. carried on a rather extensive development of the production of ethylene and propylene chlorhydrins from the vapors of cracked petroleum products in the years 1912 to 1918,¹⁴ but as far as known without commercial success. During the period of the war under Government subsidy a large number of private plants were equipped with ethylene from alcohol generation units, as well as the Government arsenals, and at the time of the armistice good progress was being made toward the goal of producing 200 tons per day of mustard gas by the ethylene-sulphur monochloride process.

Since 1918 many of the plants both here and abroad, equipped for ethylene production, have continued to operate on making certain chemical specialties from ethylene generated from alcohol. Also the production of isopropyl alcohol from the propylene of cracked petroleum vapors has been announced almost simultaneously both in Germany and in the United States. At present writing this product is being made by several companies by processes varying in no broad way from Berthelot's original process. The British Government, realizing the military necessity of a large ethylene supply, has fostered the development of an ethylene industry in that country, and as a result the industrial absorption of the ethylene contained in coke-oven gases by sulphuric acid has been carried out with apparent success by the Skinningrove Iron Works,¹⁵ among other companies. To the credit of these present-day chemists who are now developing these products commercially, it must be freely granted that they have indeed contributed greatly along technical and engineering lines to make their processes succeed where earlier efforts failed. To them, second only to the early pioneers, is due full credit for the success of these adventures.

REACTIVITY OF OLEFINE GASES

During this extended period of more than 125 years the chemists of the world have not been inattentive to the interesting possibilities offered by the reactivity of the olefine gases, but on the contrary have carried on series after series of brilliant researches in this field which constitute today one of the most fascinating chapters of organic chemistry. It is beyond the scope of this paper to attempt to review this mass of accumulated knowledge which is already available in so many places and which has already been summarized excellently by others.¹⁶ That the technical development has not kept pace with the promise given by the unselfish work of the early path-makers is perhaps unfortunate, but with a competent start now well made it holds much in prospect for the coming years.

The sources of crude material from which the olefine

gases may be isolated are indeed quite widely distributed. These gases do not occur naturally, but their occurrence in artificially prepared mixtures has been generally known for many years due to the activity of many private research organizations as well as the Government bureaus which have published the analyses of gaseous mixtures from many sources. The easiest and most reliable source of the individual olefines is from the corresponding alcohol as has been referred to above, from which the gases may be obtained respectively in a pure state. This is best accomplished by passing the vapors of the alcohol over a suitable catalyst such as kaolin, with or without steam, at a temperature varying from 350 to 600 deg. C., according to conditions.¹⁷ This fact has been common laboratory knowledge for many years, and it was to the pure ethyl alcohol that the Government turned in time of emergency, when the prompt production of large quantities of pure ethylene became a matter of national necessity. Denatured ethyl alcohol is universally obtainable, and while the propyl and isopropyl alcohols have hitherto been less accessible, it appears that they will from now on be much better known. Still other ethyl and propyl compounds, such as the chlorides, acetates, etc., will also yield the corresponding olefine gas by a similar reaction to the above, but as these compounds are all commercially derived from the alcohol, their industrial importance as a source of the gases is but secondary.

OCCURRENCE IN ARTIFICIAL GASEOUS MIXTURES

A much more widely distributed source of these hydrocarbons exists in the gaseous mixtures obtained from the pyrolysis of organic matter. This includes coke-oven gas from the coking of coal, illuminating gas prepared from high-temperature decomposition of either oil or coal or both, the gases from the cracking of petroleum oils, the gases from the distillation of hardwood, oil shale, rosin, lignite, peat and many other materials of similar nature, which are now commonly treated for purposes other than the production of the olefine-containing gas mixtures. To a lesser extent there is also a certain olefine content in producer gas and blast-furnace gas. As will be readily recognized, this list includes practically all of the sources of artificial gas, and almost without exception these gases are used exclusively for the generation of power, heat or illumination. The olefine gases in these mixtures usually occur together with a variety of saturated hydrocarbons, hydrogen, nitrogen, carbon dioxide, carbon monoxide, aromatics and other higher olefines, commonly liquid when in the pure state. In some cases, as with the gases from the high temperature cracking of oils, the combined ethylene and propylene content may run as high as 35 to 45 per cent by gaseous volume under the most favorable conditions. In the more usual cases the combined olefine gas content is under 10 per cent and in most of the largest scale sources, such as coke-oven gas, a true olefine gas content of from 2 to 4 per cent is common. In the producer gas and blast-furnace gas it rarely exceeds a few tenths of a per cent. In all of the above-mentioned cases, the olefine content being an inconsiderable item at present in the operation of the processes concerned, the variations in analysis are rather wide, and no single analysis is of particular value.

In any particular case the problem of absorbing the desired olefine gases by chemical processes or that of

isolating them in the pure state is a special one for the material at hand. In the limited amount of past work on this subject the general procedure of finding a specific absorbent, such as sulphuric acid, or of using a specific reagent, such as chlorine, to form a condensable reaction product has found preference when handling such gaseous mixtures. On the other hand, a distinct advantage lies in having a pure gaseous material to deal with when carrying out chemical reactions. The former general process has the advantage of low costs, and for certain purposes at least the availability of the pure olefines from the alcohols successfully avoids the necessity of purifying the gases from the complex mixtures in which they occur. In the writer's work a novel process of producing the olefine gases is in use. Patents are now pending on the processes involved.

For use as such in the pure state when conveniently supplied to the market in compressed or liquefied form,

as is common today with other industrial gases, it seems probable that both ethylene and propylene will find extensive application. These gases have physical properties as shown by the accompanying table.

The values given are believed to be reliable, although certain ones may be subject to slight revision.

INDUSTRIAL UTILIZATION

It may be readily seen that gases with these characteristics will find application in many ways. It is not expected that any hydrocarbon gas can rival acetylene, which possesses its unusual properties as a direct result of its highly endothermic nature. On the other hand, the olefine gases possess high fuel value, and for cutting and light welding may be expected to find favor in view of their easier transportation. It has also long been well known that illuminating gases owe their illuminating power largely to their olefine contents. The supply of these "illuminants" in pure form may now be expected to prove of value in special cases of illumination and heating, such as in country homes and the like. Furthermore in earlier scientific work seeking low temperatures ethylene has already been used as a refrigerant.¹⁵ The similarity of propylene in its boiling point to anhydrous ammonia would suggest its possible use as a refrigerant, for refrigeration at temperatures nearer normal.

More important than the direct use of the olefine gases for themselves is the pronounced chemical reac-

tivity which characterizes them. The chemical literature contains actual accounts of hundreds of reactions which may be carried out involving ethylene and propylene. It is unnecessary to state that all of these do not lead to commercially valuable products, but certain of them do show a means of building up from these materials substances which rank among the most important of the commercial chemicals. In addition to denatured alcohol, isopropyl alcohol, ethyl ether, ethylene chlorhydrin, ethylene glycol, ethylene dichloride and "mustard gas," which have already been mentioned above, there may be added diethyl sulphate, ethylene oxide, oxalic acid, formaldehyde, formic acid, acetone, propylene glycol, propylene chlorhydrin and many others, in addition to the simple combinations and derivatives of the above products themselves. It will be the purpose of following articles to describe certain of these new commercial products which perhaps are still not familiar to the chemical public, and to point out how these new materials may find their way into our rising American organic chemical industry.

Our national resources, which supply the greater part of our needs so amply from home, are also equally able to provide for an extensive ethylene and propylene industry. Consequently since modern military developments have shown that in addition to the toxic gases, acetone, alcohol, ether and such organic chemicals are also indispensable to national defense, therefore the olefine gas utilization, as soon as commercially developed, will find itself elevated to the position of one of the key industries to our modern commercial chemistry.

(Part II, on Diethyl Sulphate, will be published in a subsequent issue.)

A Survey of Library Service to Engineers

That the engineering profession has taken a leading position in the development of research and informational facilities is one of the facts disclosed by a recent survey made by the Special Libraries Association. As a result of this investigation more than 1,300 special libraries were discovered, many of which are largely concerned with engineering, technology, electricity, chemistry and industrial management.

Engineering libraries of various types are maintained by national and local engineering societies, by colleges and universities, by large manufacturing companies, by professional engineering firms, by public utility companies and by various other agencies. Some of these libraries have been in existence for many years, but many others have only recently been established. The most complete and comprehensive collection is that of the Engineering Societies Library in New York City.

Some of the engineering libraries report interesting special features. For example, the Boston Society of Engineers has a collection of books "written by engineers on subjects other than engineering." The library of a professional engineering firm reports a collection of from 100,000 to 200,000 trade catalogs covering a wide range of industries. One university library possesses 4,200 lantern slides on engineering subjects. Many of the engineering libraries have given special attention during the last few years to the collection of military, naval and aviation engineering literature.

The complete findings of the Special Libraries Association's survey have recently been published in the form of a "Special Libraries Directory," edited by Dorsey W. Hyde, Jr., president of the association, Mills Building, Washington, D. C.

Impact Properties of Various Steels

Cylinders of Steel, Centrifugal Cast, Were Sectioned and Tested—A Set of Steel Bars, With Increasing Carbon Content, and Some Steel Castings Were Tested After Various Heat-Treatments—
A Comparison of Impact for Forged and Cast Steels

By F. C. LANGENBERG

Metallurgist, Watertown Arsenal, Watertown, Mass.

THE author of this article recently presented the results of certain investigations on the shock value of steel castings to the American Society for Testing Materials.¹ Requests for additional observations on the same subject have since been received, and the writer has therefore considered that the following further account of these and other investigations may be of general interest.

In the previous article results of tests were given showing the effect of phosphorus on cast steel made in the converter, the effect of different carbon and manganese contents on cast steel made in a small basic electric furnace, the effect of various heat-treatments on cast steel made in the acid open-hearth furnace, and results of impact tests made on forged steels of different carbon content and submitted to various heat-treatments.

Results are now given of an investigation of steel castings made by the centrifugal process, the effect of certain heat-treatments on cast steel, further details on the effect of heat-treatment on forged steels of different carbon content and a comparative summary of the impact strength of the various steels considered.

Three cylinders were received, each approximately 71½ in. long and 10.9 in. in diameter. The three castings were numbered 1, 2 and 3, respectively.

¹Noted in CHEM & MET. ENG., vol. 24, p. 1146, June 29, 1921.

The sections from castings lettered from A to J, inclusive, were then polished and etched with iodine. One-half of casting No. 1 was polished throughout its entire length and also etched with iodine. The result of the etching of a ring from casting No. 3 (Fig. 1) shows the existence of circumferential bands and also the persistence of the original ingot structure. The bands proved to be ferrite by microscopical examination.

Rings B and F from casting No. 3 were rough-machined on the interior and then forged to a wall-thickness of 1½ in. The length of the ring was not increased by this operation, the decrease in the diameter of the cylinder wall being made by an increase in the diameter of the ring. Fig. 2 shows the location of the samples taken from rings B and F in the forged condition and the physical tests obtained are given in Table III.

FIG. 2. LOCATION OF SPECIMENS LISTED IN TABLE III

Sections of forged ring F were then heat-treated as follows: Heated to 800 deg. C. and held for 1 hour, after which they were quenched in water. Subsequent to the quenching operation they were drawn at 675 deg. C. The sections of cast ring G were similarly heat-treated. The location of the test specimens taken from the sections so treated are shown in the drawing, Fig. 3. There is thus available for comparison tensile and Charpy tests from two rings, ring F being forged and heat-treated and ring G being treated without forging. The physical tests resulting are shown on Table IV. The forged and heat-treated ring shows better ductility than the cast and heat-treated ring, although the ductility was exceptionally good for both specimens, as was likewise the Charpy value. The Charpy values obtained upon the heat-treated casting are superior to those generally obtained upon gun forgings. This statement

TABLE VI. CHEMICAL COMPOSITION AND CHARPY VALUES OF HEAT-TREATED BAR STOCK

Chemical Composition						Heat-Treatments							
C	Mn	S	P	Si	Cr	Original	V ₁	V ₂	V ₃	V ₄	V ₅	V ₆	V ₇
0.14	0.45	0.035	0.018	0.131		45.39	28.01	38.10	47.18	47.95	49.50	48.34	52.61

The heat-treatments were as follows: Original, as received; V₁, annealed just above A_{c3}; V₂, hardened in water from just above A_{c3}; V₃, hardened in oil from just above A_{c3}; V₄, quenched in oil from just above A_{c3} and drawn at 375 deg.

C.; V₅, quenched in oil from just above A_{c3} and drawn at 460 deg. C.; V₆, quenched in oil from just above A_{c3} and drawn at 560 deg. C.; V₇, quenched in oil from just above A_{c3} and drawn at 650 deg. C.

The quenching temperatures were:

Carbon	Quenching Temperature Deg. C.	Carbon	Quenching Temperature Deg. C.	Carbon	Quenching Temperature Deg. C.	Carbon	Quenching Temperature Deg. C.
0.14	866	0.46	819	0.71	800	1.22	790
0.18	858	0.49	816	0.83	795	1.39	790
0.32	836	0.57	809	1.01	790	1.46	790

All pieces were held at quenching temperature 20 minutes, and at the drawing heat 30 minutes.

should be made with the reservation that the elastic limit and tensile strength are not so high as gun forgings from which Charpy bars have been taken.

Material used for test consisted of slabs 1½ in. thick which were cut from a 10-in. round ingot, cast in the foundry of Watertown Arsenal.

The chemical analysis was C 0.30, Mn 0.62, Si 0.181, P 0.038, S 0.038. Three heat-treatments were applied—

Treatment A: Heated to 900 deg. C., soaked 2 hours at this temperature and water-quenched, followed by drawing 2 hours at 650 deg. C. and furnace-cooled.

Treatment B: Heated to 900 deg. C., soaked 2 hours at this temperature and furnace-cooled.

Treatment C: Heated to 950 deg. C., soaked 2 hours at this temperature and cooled in air, followed by drawing 2 hours at 500 deg. C. and furnace-cooled.

The impact results as given by the Charpy machine were as follows: Treatment A, mean of seven tests, 14.35 ft. lb.; treatment B, mean of eight tests, 11.33 ft. lb.; treatment C, mean of eight tests, 11.87 ft. lb.

An inspection of the mean results shows that water-quenching has raised the impact strength from 11.33 to 14.35 ft.-lb., while air-chilling and drawing at 500 deg. C. raised the impact strength but slightly.

The chart Fig. 4 shows graphically the results of Charpy tests on twelve forged steels mentioned in the previous article. A repetition is given of the chemical compositions and heat-treatments in Table VI.

FIG. 4. IMPACT RESULTS OF FORGED STEELS OF INCREASING CARBON CONTENT UNDER VARIOUS HEAT-TREATMENTS

FIG. 5. COMPARATIVE IMPACT VALUES OF CAST AND FORGED STEELS

In the chart (Fig. 5) are graphically summarized and compared the impact results of the various cast and forged steels referred to in this and the previous article.

The diamond mark represents steel castings of "Experiment No. 1" of the previous article, before the American Society for Testing Materials.¹

The castings each contained 0.42 carbon and 0.86 manganese. They were annealed at 950 deg. C. for 2 hours and air-chilled, then drawn 4 hours at 500 deg. C. Steel A represents a phosphorus content of 0.043 and steel B represents a phosphorus content of 0.104.

The plus sign represents castings having different carbon and manganese content. The castings had been air-chilled at a temperature of 900 deg. C. The carbon content is shown on the chart and the corresponding manganese content is as follows:

C	Mn	C	Mn
0.44	0.93	0.222	1.29
0.27	1.08	0.33	1.54
0.298	1.3	0.346	1.76

The circle represents steel castings produced by the centrifugal process. Details of treatment, etc., are given above.

The minus sign represents cast steels heat-treated in three different manners, as described above.

Acknowledgment is made to Captain W. B. Bently, now professor of chemistry, Ohio University, who conducted the tests on the investigation of steel castings made by the centrifugal process, and to Nicholas Richardson, research engineer, Watertown Arsenal, who has assisted in compiling data on forged steels.

University Researchers Should Patent Discoveries in Their Own Names

BY WILLIAM J. HALE
The Dow Chemical Co.

IN A recent article by William Hoskins and Russell Wiles on the "Promotion of Scientific Research," which appeared in *CHEMICAL & METALLURGICAL ENGINEERING* (vol. 24, p. 689, April 20, 1921), we meet with a novel proposition—namely, that universities should patent the inventions of their research men and lease the same to the industries, the proceeds to be applied directly in the continued furthering of research.

The suggestion is indeed worthy of study from the standpoint of both industry and university. The paper is replete with rich suggestions and advice, but the plan in itself affords no ray of hope for financial aid to university research. My critical attitude in this connection will better be condoned if I attack first the weak points and then bestow praise upon the numerous commendable statements made by these authors on the subject of research.

PARTICULAR RATHER THAN GENERAL PATENTS OF INDUSTRIAL VALUE

1. Foremost of all arguments against the proposition, it must be asserted that patents of general processes are rarely of much pecuniary value. I cannot recall a single instance where a patent on some basic principle yielded a revenue worthy of consideration. True, a number have been sold outright at handsome prices, such as the Nernst lamp, for instance, but the purchasers here, as elsewhere, are the financial losers.

The early basic patents would seem to serve primarily the purpose of an inspiration for subsequent inventors. The basic patent of the sewing machine—an eye in the point of the needle, unheard of in all preceding centuries—yielded nothing. The Selden patent on internal combustion engines with clutch release is at the basis of the great automobile industry, but it survived only a few years till broken.

It is, therefore, the application of some particular phase of these basic discoveries alone that claims the attention of industrialists. It is the particular rather than the general that commands industrial value. No sooner is a new principle promulgated than each conceivable adaptation of it is visualized in every industrial research laboratory in the country. So much better equipped than the average university laboratory for purposes of detailed practical applications, there is little wonder that the industrial scientist can evolve new points of value and points equally as patentable as the general principle itself. In other words, a university laboratory could not be expected to give more than the merest generalization in its claims for patents, and by the time the patent was granted there would be so many more patents pending on details, and especially upon new ideas growing out of the original patent, that the university itself might be forced to pay an appreciable amount in royalties to subsequent inventors in order to present anything attractive for lease to industry.

2. Industries nowadays patent everything. We have had costly experiences when acting to the contrary. We patent to protect ourselves and not to claim any wonderfully conceived new ideas. When thus protected in our operations, we proceed with comparative impunity, as we know we cannot be interfered with. The

patents of others little interest us any more than to direct the attention of our research men to still better adaptations of our own particular manufacturing processes.

DIFFICULTIES ENCOUNTERED WITH MORE THAN ONE LICENSEE

3. If there appears some altogether new patent of which we wish to make use, naturally it is to our advantage to buy it outright or lease it on some very small royalty. If another concern desires to lease this same patent, I doubt if we should continue with our lease unless our costs of production were materially lower than our competitor's. It is not worth while to take on extra competition unless you have a material advantage at several points. So soon, therefore, as a university owning rights to a patent began to lease the same to several companies (she never could get much pecuniary assistance from leasing to one company alone) so soon would the value of the patent depreciate and sooner or later the free use of the patent would be forced upon her—a fact made apparent as soon as the university failed to prosecute a single concern using the patent without license. The regular licensees, paying their fees for their own protection, have a right to assume that their leased rights will be guarded by law.

4. A good chemical staff at a large university today with constant and persevering attention to research, where the ultimate goal is financial aid to the university, will scarcely be able to evolve much of a basic nature in the course of a college year. If, however, its concerted action is directed to some particular small problem there is reason to hope for positive results—but think of the "leaks"! You might just as well announce the work at the start. University men are the last to anticipate the valued factors in their researches. In other words, a corps of men at an industrial plant are so much more advantageously situated with scientific, material and legal equipment that a new idea, no matter how crude its conception, can be safely secured for their industry long before the university men realize what they are at work upon. When, however, the university man works alone or with a close collaborator and the question of time is left out of consideration, we find many discoveries to his credit, and patents have usually followed free from outside interference.

THE QUESTION OF PATENT COUNSELORS

5. I know of no type of university man willing to grant that patent counselors could be helpful to university scientists. The scientific men fully realize that these counselors are anything but scientists. They may have had some scientific training, but they are not capable of diagnosing scientific problems save where exactly similar questions have been a matter of study between them and the Patent Office. The only possible help from the patent attorneys would be in the form of a comprehensive report from them on all patents bearing on the general processes involved. With such reports at hand, the investigator cannot do better than consult privately with industrial leaders, men of high standing in their profession and in their community. These men and these men alone are the only men who can help the inventor. Though this is, indeed, solid truth, some way or other I just can't picture to myself the solicitation of advice from industrial leaders on the part of our university professors.

6. There is nothing dishonorable in a university scientist seeking a patent. On the contrary, he gains enormously thereby in international prestige. Of course he usually is condemned at home by the university drones unable to comprehend the value of ideas other than their own; but such childish criticisms are negligible. No true scientist doubts for a moment the rights of a man to patent his own inventions. The great majority of our well-known chemists of England, France and Germany are holders of patents in their respective countries. In this country the so-called baneful influence of the industries has been held over young scientists as a sword of Damocles, so to speak, but I assure you the sword is now sheathed. The real inventor or discoverer should have a right to his own ideas and he alone should reap what little benefits may accrue therefrom.

NEED FOR GREAT INCREASE IN SCIENTIFIC RESEARCH

This paper of Messrs. Hoskins and Wiles presents a number of points in which one must concur with the highest commendation. "An immense increase in scientific research is perhaps the most important future step for the welfare of this country." This is a truth of such limitless scope that we can scarcely realize its import. These authors avow that researches must begin as pure science and take the direction of applied science in order to raise the standards of the physical well-being of our people. At this point Messrs. Hoskins and Wiles introduce the crux of the whole matter: "Industry is taking care of the application of science." The university therefore must stimulate the researches in pure science, else "the stream will dry up."

The establishment of a 10-year period for research in pure science for a man after receiving his doctorate is all well enough and admirable for the future of both university and industry, no matter where the young man casts his lot, but the salary paid is usually so small during the early years of this constructive period that barely a living wage is afforded the scientist. Physically he may become more or less a wreck.

The financing of these men and their investigations brings out the proposal which the authors have suggested. They argue that the industries will gladly pay for patents thus obtainable after assignment to the universities. This is all true enough, but, as stated in my foregoing criticism, there will be so little of patentable nature that the university and the investigator will reap greater renown if he goes on his quiet way with never a thought of patent or legal advice until he himself runs across something which he recognizes is new and which he is anxious to secure in his own name. A man in this age unable to recognize at least the partial value of his discoveries is really to be pitied and actually to be classed as a moron; I doubt if universities should countenance his presence too long among the more intellectual. The custom of university scientists in presenting purely scientific papers is highly to be commended. I would that we industrial men could get the time to contribute likewise in this capacity. Just where Messrs. Hoskins and Wiles find authority for the statement, "It seems to be agreed that to permit members of the scientific faculties at our universities to patent their discoveries for their own personal benefit is an entirely wrong procedure," is unknown to me. It strikes me as of ancient mariner lore—antique in thought maybe, worthy of admiration

and praise for the goodly influence in the past, but in this dynamic age certainly out of harmony. In practically every university today there are professors of chemistry who hold patents and there will be more and more as university men awake to their possibilities.

The one point which Messrs. Hoskins and Wiles would bring against this right to patent in the name of the scientist is that this action may tend to restrict the direction of research into lucrative fields, especially in the realms of applied science. This indeed is the strongest criticism of the procedure and one in which I have interested myself to a large extent. In order to avoid this pitfall I have advocated an actual payment for research in pure science. (*J. Ind. Eng. Chem.*, vol. 12, p. 690, 1920.) Somewhat later, when industrial conditions are improved, I hope this question can be brought up again. To deprive the university scientist of the right to patent in his own name and reap whatever profits accrue would indeed destroy about the last vestige of incentive left to him. High salary and high recognition with promotion come only slowly, owing to the dead timber still standing; the university therefore cannot safely consider a step so likely to drive its research men into research and industrial institutes.

SPECIAL RESEARCH FELLOWSHIPS

The founding of special research fellowships, particularly where the donor is a scientist himself and directs (though indirectly) the research work of the Fellow, is an admirable example of what we may hope for under favored conditions, and with this practical suggestion I believe Messrs. Hoskins and Wiles have admirably described a means of co-operation of university and industry.

Metallurgical Examination of Broken Crankshaft

A broken crankshaft from a 10-ton ammonia refrigeration machine was submitted to the Bureau of Standards for examination by one of the other Government departments. The material proved to be inferior in that it was decidedly porous and showed evidence of not having received sufficient reduction in forging. The break which occurred was in the nature of a fatigue failure and had its origin in the angle between one of the throws and the bearing. A defect at this point had been filled in previously with arc-fused metal. Such a procedure would not necessarily lead to failure had the defect been located elsewhere, but at the point in question the stresses are much higher than at other points on the shaft, and the break once started would be propagated rapidly owing to the unsound character of the steel.

Present Status of German Leather Industry

A cablegram from the representative of the Department of Commerce, Berlin, reports that German tanneries are producing calfskins, patent leather and kid leather up to 65 or 75 per cent of their pre-war output. The tanners are receiving adequate supplies of raw hides and skins to keep the industry occupied. France is supplying 70 per cent of the calfskins and 90 per cent of the kid leather. Denmark and Sweden are other sources of supply; England sends additional patent leather, Russia virtually nothing. Labor conditions in the leather industry are satisfactory, with almost no unemployment. Present wages per hour of 6.25 to 8 marks compare with 1913 rate of 45 to 65 pfennigs per hour.

Contrast Etching for Metallographic Specimens

BY HENRY S. RAWDON* AND MARJORIE G. LORENTZ*

THE terms "contrast" etching and "plain" etching are used to designate the character of the results obtained with different reagents upon any type of alloy and particularly those consisting of one constituent such as the "pure" metals, the α brasses and bronzes, β brass, etc. Microscopic examination of sections of such materials after plain etching usually reveals only the grain boundaries, as a network of black lines together with such extraneous features as inclosures. The grains themselves show no "individuality" other than that of shape and size. However, in the same material after contrast etching, each grain has an individuality of its own which is the result in large measure of its relative brightness as compared with the neighboring grains. The plain etch-pattern bears much the same relation to the contrasted one as a simple outline sketch of a group of objects does to the completed drawing of the same. For general purposes, the contrast etch-pattern is usually preferred, although in some cases, particularly for examinations at high magnification, the plain etching is the more desirable one to use.

Contrast may be developed in at least two very different ways. If the polished surface of the specimen

FIG. 2. MICROSTRUCTURE OF BRASS ETCHED BY MEANS OF HYDROGEN SULPHIDE. $\times 85$

a. α brass (Cu 67, Zn 32, Pb 1 per cent) etched with 10 per cent solution of silver nitrate. Note the absence of contrast.

b. Same specimen as a, which after polishing was suspended in an atmosphere of hydrogen sulphide for 1 minute, and acquired a surface film of sulphide. Black spots mark inclusions of lead.

c. The specimen after being etched as in a was placed in hydrogen sulphide as in b. The contrast of the etch pattern produced was much less pronounced than in d.

d. The specimen after being filmed by means of hydrogen sulphide as in b was etched with silver nitrate solution as in a. A brilliant contrast results.

The nature of the roughening produced by very deeply etching a specimen of brass (copper 69, zinc 31 per cent approximately) is shown in Fig. 1. The contour of the roughened surface was revealed by using sections perpendicular to this surface, precautions being first taken to protect it by means of a coating of electrolytically deposited copper. The micrographs plainly show the regularity in the roughening of a crystal produced by etching and also that it conforms to the crystalline orientation of the grain as revealed by the etching pits. This means of producing contrast is well understood and has been frequently described. The second method, however, is not so well known.

It is often desirable in the study of the microstructure of metals to produce contrast without much roughening of the surface. This may be accomplished by the use of reagents which cause the formation of a very thin film on the surface, the thickness of which varies from grain to grain. This effect has been described in considerable detail for copper¹ and is usually attributed to an oxidation film. The part that such films play in contrast etching may be revealed rather strikingly, as shown in Figs. 2 and 3, by a double etching process in which the filming operation is separate from that of etching.

Hydrogen sulphide gas may be used as a convenient means for producing a thin film on the specimen and an aqueous solution of silver nitrate as the reagent for etching which, of itself, produces little if any contrast (Fig. 2a). When the slightly warmed polished brass specimen (copper 67, zinc 32, Pb 1 per cent, approximately) was suspended in a bottle by hydrogen sulphide to which a drop of concentrated hydrochloric acid had been added to accelerate the action, a film having the appearance shown in Fig. 2b was produced. (It may be noted here that hydrogen sulphide of itself,

FIG. 1. ROUGHENING OF THE SURFACE AS A RESULT OF PROLONGED ETCHING. $\times 500$

A polished section of an α brass (Cu 69, Zn 31 per cent) was etched 12 hours in 50 per cent copper ammonium chloride and a section perpendicular to the etched face was then examined after etching with copper ammonium chloride. Note the similarity in orientation of the notches in the etched surface of a, which represents a portion entirely within a single crystal. Note in b how the orientation of the notches of the etched surface is the same as that of the etching pits within the crystal.

is etched sufficiently, the surface metal is dissolved and a differential roughening of the various grains will result as the crystalline facets are revealed within the boundaries of the different grains. Since the orientation of all the facets within any particular grain is the same, it follows that practically all the light incident upon such an etched surface of a crystal will be reflected in a definite manner. The direction of the reflected beam varies for different grains depending upon the difference in the orientation of the crystalline facets from grain to grain. Thus a crystal-grain will appear light or dark according to the position of the eye of the observer with respect to the beam reflected from this crystal.

FIG. 3. MICROSTRUCTURE OF CAST BRONZE. $\times 85$

a. Cast zinc bronze (Cu 88, Sn 10, Zn 2 per cent) etched with 10 per cent solution of silver nitrate. Adhering silver covers the eutectoid constituent.

b. Specimen a which, after polishing, was placed in an atmosphere of hydrogen sulphide for 1 minute.

c. Specimen a, filmed by hydrogen sulphide as in b, then etched with silver nitrate as in a.

d. Specimen a, etched with silver nitrate and then exposed in hydrogen sulphide as in b.

A brilliant contrast is produced. The adhering silver covering the eutectoid (see a) protects this constituent from the action of the sulphide and thus increases the contrast.

particularly if dry, has an almost negligible effect upon a metal; a trace of acid fumes, however, quickly causes a heavy sulphide film to form.) No evidence of crystalline structure was revealed by the hydrogen sulphide attack. On the other hand, when a specimen etched by means of silver nitrate solution was introduced into the hydrogen sulphide atmosphere, the sulphide film formed on certain crystals with greater readiness than on others, so that a slightly contrasted etch-pattern resulted (Fig. 2c). However, the best results by far were obtained by first producing a uniform sulphide film on the polished surface of the specimen and then etching the filmed sample in the silver nitrate solution (Fig. 2d). Such a procedure gave excellent results with α brasses and $\alpha\beta$ brasses. With cast bronze (copper 88, tin 10, zinc 2 per cent), excellent results were obtained by producing the sulphide film on the etched surface rather than by etching the previously filmed specimen (Fig. 3). It will be noted in Fig. 3a that after etching with silver nitrate, the eutectoid constituent of the bronze remained coated with a deposit, presumably precipitated silver. This deposit protected this constituent from the action of the hydrogen sulphide gas to some extent when the etched specimen was introduced into the gas and so added to the contrast of the resulting etch-pattern.

The fact that the results given above are of rather

FIG. 4. MICROSTRUCTURE OF ANNEALED BRASS. $\times 85$

The polished specimens were heated for 10 minutes on a hot plate in the air, so as to produce a uniform oxide film. The oxidized specimens were then etched with 10 per cent silver nitrate solution.

general application and do not depend upon any peculiar properties of the sulphide film was demonstrated by using oxide films instead of sulphide. Specimens of brass were gently heated on a hot plate in the air until they were uniformly coated with oxide and were then etched with silver nitrate solution. The very striking contrast pattern produced as a result of this procedure is shown by Fig. 4. A somewhat similar effect sometimes results when a specimen is polished too long on a wheel which has been allowed to become nearly dry. Ferrite, for example, may under such circumstances develop a black-and-white contrast pattern upon etching instead of showing its usual appearance.

For demonstration purposes, one is restricted somewhat in the choice of reagents used, since it is necessary that the solution used be one that produces a "plain" etch-pattern. For practical use, of course, this limitation does not hold.

Development of the Gas Industry

A survey completed by the American Gas Association reveals in striking degree the magnitude to which the gas service of the nation has grown. Some interesting statistics are:

Gas furnishes the cooking heat, and in many cases illumination, in the homes of over 49,000,000 citizens.

Communities served with gas number 4,600 and meters 8,580,000, the gas mains totaling 68,300 miles.

To make the gas consumed by households and industry last year required 8,500,000 tons of bituminous coal, 2,000,000 tons of anthracite coal, 1,500,000 tons of coke, and 960,000,000 gal. of oil.

Hotels, clubs, restaurants and institutions using gas for cooking number 71,490, while those using it in part number 13,776.

The tremendous use of gas for industrial purposes is seen in the fact that 25 per cent of the nation's consumption is now by manufacturing concerns, it being used in over 1,500 different processes. The steady growth is recorded in the following table, compiled from Brown's Directory of Gas Companies:

GAS SALES BY YEARS, 1901 to 1920

Domestic Production and Imports of Hides and Skins, 1920

The domestic production of hides and skins in the United States during 1920 exceeded the imports of foreign ones by 150,000,000 lb. The estimated output for the year was 849,530,000 lb., the imports aggregated 700,113,000 lb.—both on a "green" basis. These totals, as tabulated in *Commerce Reports*, included:

Kinds of Hides and Skins	Domestic Production,* Lb.	Imports† Lb.
Cattle hides.....	673,676,000	334,475,000
Calfskins.....	115,954,000	52,035,000
Sheep and lamb skins.....	29,719,000	112,523,000
Horse, colt, ass.....	30,000,000	21,890,000
Buffalo hides.....		20,727,000
Goatskins.....	181,000	150,074,000
Kangaroo and wallaby skins.....		1,389,000
All other hides and skins (exclusive of furs).....		7,000,000
Total.....	849,530,000	700,113,000

* Estimated.

† Converted to a green basis, 1 lb. of dry equal to 2 lb. of green.

Recent Developments in the Sulphuric-Acid Industry—II*

Review of Such Modern Tendencies in the Chamber Process as the All-Masonry Construction of Towers, the Introduction of Interchamber Towers and So-Called Cooling Chambers, and Recent Changes in Design of Acid Chambers and Accessories

BY ANDREW M. FAIRLIE
Consulting Chemical Engineer

IT IS the intention of the author to confine himself in the present paper to a review of the more recent advances which have been made in the manufacture of sulphuric acid, particularly as these developments affect the design, construction and operation of Glover and Gay-Lussac towers and of chambers and their accessories.

Acid-proof masonry without lead curtains, as applied to Glover-tower construction, is a development of recent years. The first all-masonry acid-proof towers built in this country were erected at Nitrolee, S. C., in 1911, of stone and an acid-proof cement imported from Germany, and were used as nitric-acid towers. Later, in 1914, all-masonry towers were built for a phosphoric-acid plant at Mt. Holly, N. C., and these towers, so far as known, were the first all-masonry towers to be built of American-made chemical brick and cement. The bricks for the Mt. Holly plant were furnished by the B. Mifflin Hood Brick Co., of Atlanta, Ga., and the cement by the Chemical Construction Co., of Charlotte, N. C. The first all-masonry acid-proof towers for use in a sulphuric-acid plant were built at Macon, Ga., in 1914. Since then many acid-proof all-masonry towers—Glovers, Gay-Lussacs and concentrators—have been built in all parts of the country.

The steel supports of a Glover tower designed by the Chemical Construction Co. and also the manner of packing the tower are shown in Fig. 4. Manufactured forms of packing ordinarily are not used in the Glover tower, on account of the danger of cracking and collapsing under the intense heat. The Glover tower is usually packed with checkerwork chemical brick, with graded sizes of lump quartz, or with a combination of the two, the quartz on top.

Different views of the Glover and Gay-Lussac towers built for the new 250-ton plant of the Union Acid Works, Baltimore, Md., are shown in the accompanying illustrations. Fig. 5 shows the masonry Glover and Gay-Lussac towers under construction; Fig. 6 the masonry Glover towers (in left foreground) and masonry Gay-Lussacs (in left background) completed, with lead draft pipe from the last chamber entering the bottom of the first Gay-Lussac; Fig. 7 acid distributors on top of Glover tower and upper part of first Gay-Lussac tower, with acid distributors on top. In this photograph the method of staying the brickwork with angle-irons, tee-irons and tie-rods is clearly shown.

A form of tower construction recently designed for hot gases and acids is controlled by Perry & Webster, Inc., of New York City, and has been described and illustrated by Wells and Fogg in Bureau of Mines Bulletin No. 184.⁹

At one or two chamber plants recently constructed so-called "cooling towers" or "cooling chambers" have been introduced. The plants where such "cooling towers" have been installed have chambers of unusually large cubic capacity in proportion to total lead surface of tops and curtains. It is to compensate for the deficiency of heat-radiating surface of such large chambers that the small "cooling chambers," which have an unusually small volume of cubic space in proportion to area of lead surface, are installed. Properly speaking, the chambers themselves are just as truly cooling chambers as are the smaller structures to which the name "cooling chambers" has been applied. As the "cooling chambers" are made of the same materials as the chambers proper, their object is not to effect any necessary preliminary cooling of the gases prior to admission into the large chambers, as obviously gases hot enough to damage the large lead chambers would also damage the small ones. At the plant of the Tennessee Copper Co., where there were originally installed sixty-four cooling chambers 10 ft. 8 in. x 10 ft. 8 in. x 70 ft. high, and eight cooling chambers of the same width and height but twice the length, it was usual to find that the temperature of the gas in the second large chamber was higher than that of the gas in any of the "cooling chambers."

These cooling chambers were, nevertheless, very effective for the real purpose for which they were installed—namely, to supplement the large chambers for the radiation of the heat of the reactions and thus effect a lower temperature of the gas mixture entering the Gay-Lussac tower, resulting in improved niter recovery.

FIGS. 5 AND 6. ALL-MASONRY GAY-LUSSAC AND GLOVER TOWERS AT UNION ACID WORKS, BALTIMORE. UNDER CONSTRUCTION (FIG. 5) AND COMPLETED (FIG. 6)

No radical changes in the design of sulphuric-acid chambers have been developed in the United States within recent years. During the war the total chamber plant capacity of the entire country was vastly increased, and some of the plants whose construction was undertaken by the Government were of unusual size. Among these may be mentioned the Pratt Process plant at Little Rock, Ark., practically 100 per cent completed at the time the armistice was signed, and the 800-ton plant at Brunswick, Ga., which was only 40 per cent completed on armistice day, soon after which construction was stopped.

Construction on the two-unit plant of the Union Acid Works, at Baltimore, Md., designed and built by the Chemical Construction Co., was started in April, 1920. One unit of a capacity of 150 tons 50 deg. Bé. acid was completed in January and the second unit was completed in August of this year. Each of the two units consists of three Glens Falls sulphur Burners, one Glover tower, two Gay-Lussac towers built as one structure with a downtake for the gases between, six cham-

bers, and five interchamber towers. The Glover tower is 17 ft. square outside by 31 ft. high and has walls 18 in. thick throughout. The Gay-Lussac tower structure, with downtake included, measures outside 17 ft. x 30 ft. 8 in. x 48 ft. high, and the towers inside are 12 ft. 5½ in. x 14 ft. in horizontal cross-section. The brick walls of the Gay-Lussac towers are 18 in. thick from the foundation up to a height of 21 ft., and from that point to the top are 14½ in. thick. In each unit three of the chambers are 60 ft. x 30 ft. x 40 ft. high, two are 70 ft. x 30 ft. x 52 ft. high, and the last one is 40 ft. x 30 ft. x 52 ft. high. A view of the chambers during construction is shown in Fig. 8, wherein the chambers of the completed unit are on the right, with scaffolding for lead burners still hanging in the steel framework, and the pan of one of the chambers of the unfinished unit is in the foreground. All acid pumping at this plant, with the exception of acid delivered to the storage tanks, is done by means of airlifts. Chamber hydration will be by means of water atomizers with 1½-in. lead supply lines.

FIG. 7. TOPS OF GAY-LUSSAC AND GLOVER TOWERS OF ALL-MASONRY CONSTRUCTION, SHOWING ACID DISTRIBUTORS

FIG. 8. LEAD CHAMBERS OF UNION ACID WORKS DURING CONSTRUCTION

Shortly before the outbreak of the war a new and unusual type of sulphuric-acid chamber was brought out in England. This was a radical departure from the long-established rectangular chamber in that it was shaped in the form of a truncated cone, and was designed for the application of flowing water on the outside of the lead curtains or walls. This new chamber is known as the Mills-Packard acid chamber, a description of which appeared in a recent issue of *CHEMICAL & METALLURGICAL ENGINEERING*.¹⁰ By means of the Mills-Packard chamber the chamber space required per pound of sulphur burned has been reduced to from 3.5

FIGS. 9 AND 10. STONEWARE WATER-ATOMIZING NOZZLE FOR SULPHURIC-ACID CHAMBERS. FLANGED TYPE SHOWN ABOVE AND THREADED TYPE BELOW

to 4.5 cu.ft. The first chamber of this type was built in 1914, and its success is attested by the fact that since then 110 Mills-Packard acid chambers have been built.

Water has almost entirely superseded steam in the United States as a means of hydration in the chambers. In some plants in the Northern States steam is still

FIG. 11. INSTALLATION OF ATOMIZING NOZZLE IN TOP OF CHAMBER

C—Lead cup. S—Lead seal. N—Nozzle. W—Water supply to cock and strainer. AS—Spare seal.

used during the coldest months, owing to possible danger of freezing the water pipes unless the latter were drained. At other plants water is used throughout the year, except on the last chamber or last two chambers. As far north as Baltimore it has been found practicable to use water on all the chambers throughout the year.

The atomizers used for spraying the water inside the chambers are of various types, and include the Witclay nozzles of the Schutte & Koerting Co., the "Spra-rite" atomizing nozzles of the Binks Spray Equipment Co. and the stoneware atomizers of the Monarch Manufacturing Co. Fig. 9 shows the latest design of the Monarch stoneware atomizing nozzles, threaded type,

(U. S. Pat. 1,099,028). The disk has two or more small exposed surface grooves, molded tangential to the circumference of a concave circular space at the bottom. These grooves are equal distances apart. The water, forced through these grooves against the concave circular space, acquires a rotary motion, and is emitted from the nozzle as a fine mist. The flanged type is shown in Fig. 10. This nozzle has the advantage that, if it becomes clogged, it can usually be cleaned by inserting a pin through the small orifice (without shutting off the water supply), thereby lifting the disk and allowing the water to flush out the obstruction. If necessary, the grooves of the disk can readily be cleaned with a brush. Fig. 11 shows an installation of a water atomizer within a chamber, with lute (C) and lute cap (S) on the chamber top, and showing also the strainer and cock. The Monarch Manufacturing Co. has recently developed a new type of water strainer, to be used with their atomizer, as shown in Fig. 12, in which the strainer is not soldered, as in the old type, to the basket. The Duriron Co. has very recently developed a new type of atomizing nozzle, to be made of

FIG. 12. A NEW TYPE OF WATER STRAINER FOR USE WITH WATER ATOMIZERS IN ACID CHAMBERS

Duriron, for acid chambers, on which four patent claims have been allowed. It is not yet on the market.

The interchamber towers for the plant of the Union Acid Works at Baltimore are 7 ft. wide x 29 ft. long x 24 ft. high. There are five of these towers at each unit, and they serve as coolers and mixers of the gas on its way from one chamber to the next. These towers are built with steel frames supporting lead curtains,

FIG. 14. SPIRAL RING TOWER
PACKING BLOCK

which are lined with a 4-in. brick wall. The towers are packed with staggered rows of 3-in. spiral rings furnished by the Hood Brick Co., of Atlanta. The elevation and cross-section is shown in the drawing (Fig. 13). Atomizing nozzles for water are inserted through the lead top. Data relative to the results obtained in such towers can be found in the Bureau of Mines Bulletin previously cited by Wells and Fogg.¹¹

At some plants a packed "filter tower" has been introduced between the last chamber and the first Gay-Lussac tower, to aid in drying the gases by passing them over the condensing surfaces of the packing in this tower, before entering the Gay-Lussac.

All-masonry Gay-Lussac towers do not differ materially from all-masonry Glover towers, except in size, in thickness of walls and in packing materials. The first all-masonry Gay-Lussac towers were built with walls 8 to 10 in. thick; but it was found that acid would seep through these walls in places, and the thickness of Gay-Lussac tower walls has been increased to a minimum of 14 in., and in the newest towers the lower part of the tower walls is 18 in. thick. Two or more Gay-Lussac towers, with the downtake for gas between, are commonly built together as a single masonry structure. Such a structure is shown in the photographs of the masonry towers of the Union Acid Works (Figs.

¹¹Op. cit., p. 108.

FIG. 15. TOP VIEW OF TIER OF SPIRAL RINGS
STACKED IN TOWER

5 and 6). Gay-Lussac towers, as usually designed, are taller, and narrower in horizontal section, than the Glover tower of the same plant. At some plants a single tall Gay-Lussac tower is employed, but usually two towers somewhat less in height are preferred, and lately there has been a growing tendency to add a third tower, and the effect of this in reducing niter losses has been found to justify the expense.

During recent years the use of coke for packing Gay-Lussac towers has been gradually becoming less popular. Checkered brick or tile have been used to some extent, and since the advent of the "spiral ring," a manufactured packing block of peculiar design, this has been used by the million for packing chemical towers. The spiral ring, illustrated in Fig. 14, was patented by A. M. Webb,¹² Feb. 4, 1919. The ring was first put on the market in the early part of 1918 by the B. Mifflin Hood Co., of Atlanta, Ga. A brief description of this ring was given in the American Fertilizer Handbook for 1918¹³; and the results of some comparative tests made on different types of packing materials, of which the spiral ring was one, were quoted in a paper by Zeisberg.¹⁴ The appearance of a layer or tier of spiral rings, as stacked in a tower, is illustrated in Fig. 15. The spiral ring is not recommended by the manufactur-

FIG. 16. A NEW TOWER PACKING BLOCK, HEXAGONAL
EXTERIOR WITH HELICAL FLANGE INSIDE

ers as a packing material for Glover towers. For Gay-Lussac and interchamber towers, or for packing the acid-making units of tower systems, it is claimed to have superior merit.

A new form of tower-packing block is hexagonal in shape, and the spiral flange in the interior either extends entirely to the center of the block, or its inner edge joins a central post which fills what would otherwise be a hole, extending through the block from top to bottom. This block is shown in Fig. 16.

The hexagonal block, which has been given the trade name "Hexahelix," was developed by the author, and is protected by U. S. Patent 1,365,671. The hexagonal exterior shape has the peculiarity that six blocks can be exactly fitted around any one block, without leaving voids or spaces between blocks. The internal spiral flange is so designed that gases and liquids are compelled to pursue a spiral or tortuous course, and cannot take a vertical or short-cut course, in passing through a block. The combination of the external with the internal features of these blocks, when stacked regularly in a tower (not staggered) compels a tortuous winding flow for both gases and liquids.

(Part III will appear in a subsequent issue)

National Tube Co.'s New Plant for Hammer-Welded Pipe

Welded Pipe Up to 8 Ft. Diameter, Having Various Kinds of End Joints, Made in Highly Specialized, Massive Machinery—Details of Welding Machines and Welding Practice—Finishing Department Handles an Important Branch of the Work

BY ERNEST EDGAR THUM

PREVIOUS articles^{1 2} have discussed the general subject of welding in its branches inherited from ancient times and its recent adaptations, showing that until late years there had been no method devised for making large vessels without lap joints which would safely withstand heavy shocks and pressures. A plant built for heavy welded work by the Blaw-Knox Co. was also described, and its operation discussed in some detail. It is now the intention to present similar data on a large and well-equipped plant for making welded pipe from 24 in. up to 96 in. diameter installed by the National Tube Co. at its Christy Park Works, at McKeesport, Pa.

NEED FOR LARGE PIPE

It is doubtless well known that the smallest sizes of wrought-iron and steel pipe (less than 3 in. internal diameter) are made by butting the edges of the hot bent plate and forcing them together by drawing them through a forming die. Piping from 2½ in. up is made by lap welding; the edges of the skelp are slightly beveled, the bent plate is reheated and rolled over a mandrel. Brief mention of the methods and properties of such welds was made in the first article of this series, page 558.

While lists of dimensions, published in handbooks, show lap-welded pipe up to 36 in. diameter, such sizes are rarely obtainable, if at all. In fact any lap-welded pipe over 20 in. diameter is very difficult to make and handle. The flat skelp itself is over 5 ft. wide, the scarfing, bending, welding and straightening rolls—in fact, all the mechanical equipment—become quite bulky, the capacity of the furnaces is limited to a very few pieces, and the handling is either very laborious, or, if done by machines, fraught with possibilities of damage.

Nevertheless there are certain definite advantages of wrought over cast iron, and riveted pipes. Cast iron is of course out of the question for high-pressure work, and there are many places in low-pressure lines where it is essential that the frictional loss be held to the minimum, or, stated in another way, that the carrying capacity of a given diameter should be a maximum. The velocity of flow in riveted pipe is approximately 18 per cent less, and in cast iron, 10 per cent less, than in steel pipe having smooth walls, free from scale and projections at the joints. Making allowance for such factors, the engineers of the National Tube Co. have calculated that in a penstock, bearing 270 lb. pressure and passing 200 cu.ft. water per second, a hammer-welded pipe of ⅝-in. plate, 48 in. diameter will be the equivalent of a 52-in. pipe of ⅜-in. plate, triple-riveted longitudinal and double-riveted circular seams. Weight

of the welded pipe per ft. is 340 lb., against about 540 lb. for the riveted.

Water mains might advantageously be laid of these pipes in many locations, particularly high-pressure fire lines. Siphons on ditches and aqueducts, as well as conduits on principal water supplies, also suggest themselves. Gas lines of welded pipe would avoid many chances of loss by leakage, while much piping for hot or cold air about metallurgical plants would doubtless remain more efficient if it had fewer riveted joints. These are the principal uses which produce a demand for a considerable tonnage of large pipe and which determined the National Tube Co. to supplement its existing plants with facilities for making hammer-welded pipe 24 in. diameter and larger.

HAMMER-WELDING DEPARTMENT AT CHRISTY PARK

Sufficient room was available at the Christy Park Works (where seamless tubing and bottles are made by cupping and deep-drawing) and a new department was added to that plant.

The mill building is L-shaped, one leg consisting of two adjacent bays, of 90 ft. and 50 ft. span respectively, where the pipe is manufactured from flat plates. In the other bay, 75 ft. wide, at right angles to the foregoing, the finishing and testing is done. All this area is under cover of the most substantial kind of mill building, light and airy, and commanded by overhead cranes. Flat plates entering the plant aboard cars are handled exclusively by magnets. Serving the bending rolls, welding machines and annealing furnaces is a special charging crane.

All piping and wiring, except the 24-in. main for water gas, is placed in an underground, concreted tunnel 4 ft. x 6 ft. in dimension. This gives unusually clear overhead in the mill buildings. The service lines are not only safe from ordinary damage but are located

FIG. 1. BENDING ROLLS AND PLATE TABLE; PULPIT IN THE BACKGROUND

¹"Welding; Particularly Hammer Welding," CHEM. & MET. ENG., vol. 25, p. 553, Sept. 21, 1921.

²"Hammer-Welding Plant of the Blaw-Knox Co., CHEM. & MET. ENG., vol. 25, p. 747, Oct. 19, 1921.

so as to be readily accessible for inspection, alterations or repair. The ducts carry steam-heating lines, high- and low-pressure air and water, and the electric mains. Water gas, the fuel for the welding machines, is carried in a 24-in. main near the eaves, on the outside of the building. Producer gas for heating and annealing furnaces is conveyed from the gas house to the hammer-welding department by underground brick flues. These services are furnished by the power plants already installed for the other departments at Christy Park, except the water gas, which is generated in a separate unit, especially for the welding machines.

HEATING AND BENDING FLAT PLATE

On entering the plant the first group of apparatus consists of charging machine, heating furnace, scarfing rolls, transfer table and bending rolls. The bending rolls themselves (Fig. 1) are exceedingly powerful, and can bend a cold 1-in. plate 21 ft. long into any cylinder down to 30 in. diameter. Consequently all but the very heaviest plates are placed directly upon the transfer table, and are led into the rolls.

A thicker plate would be placed upon the charging

FIG. 4. CROSS-SECTION OF HORN, SHOWING RELATIVE LOCATION OF BEAM, ANVIL, GAS AND AIR PIPES, UPPER BURNER AND WORK

it is pushed out of the front of the furnace by the charging machine, through the scarfing rolls, stopping on the plate table, on which it travels into the bending rolls. A temperature of 1,900 deg. F. is necessary, as the bending, which requires 5 minutes or more, must be completed before the temperature drops into the brittle range.

Once in the bending rolls, it is gripped by the bottom rolls and worked back and forth, passing through the stages shown in Fig. 2 and ending as shown in the left-hand sketch. Such work may be observed in many boiler shops; about the only difference is in degree;

FIG. 2. THREE STAGES IN FORMING A CYLINDER FROM A FLAT PLATE

machine, which then moves to a correct position behind the heating furnaces. A set of chain-driven fingers slide the plate forward through the wide, low door of the heating furnace. The latter is quite similar to skelp-heating furnaces in use in other mills. It has a sand-covered flat hearth 17 x 23 ft. in area, with a low arching roof, and bordered on each side by a line of vertical ports. Regenerative checker chambers are built below the floor line on each side, so that producer gas can be used with considerable economy.

When the plate is judged to be ready for bending,

roll *B* forces the plate tight up to *A*, which is driven by a 175-hp. motor, so that the upper roll will not slip against the plate and fail to drive it over the side rolls *C* and *D*. Reaching the final stage, rolls *B*, *C* and *D* drop back to their lowest position, the end housing swings outward from a hinge near the floor line and frees roll *A*, which lifts up clear; the electric charging crane then removes the bent plate from the bending machine and deposits it on the carriage of the welding machine. All operations on this set of apparatus are controlled by one man from a pulpit.

WELDING MACHINES

Fig. 3 shows two welding machines, one designed for work up to 60 in. diameter, and the other for pipe from 48 in. to 96 in. diameter. Since the welding to be done on these units is confined to longitudinal seams on long cylinders, the carriage may be considerably simplified compared with one used for various seams on irregular shapes. It is mounted on a track so that it and its burden can move forward and backward over the anvil-bearing horn. The work rests on two sets of rollers, one forward pair and one rear pair. The beams bearing these rollers are capable of vertical movement, each pair independently, while the rollers are capable of transverse motion as well. If a weld is made on a tapered pipe, one of the roller sets is lowered a corresponding amount so the seam itself shall be horizontal

FIG. 3. WELDING MACHINES, WITH WORK IN PROGRESS

and on top. Controls are on the operating platform at the left side.

The anvil is keyed to the front end of a "horn," a heavily reinforced beam, about 12 in. deep and reaching forward about 22 ft. clear of its support (Fig. 4). The beam itself is considerably longer; it rests upon a heavy rocker bearing and extends backward, supporting a heavy counterweight. Thus the horn itself is relatively rigid and immovable; a hydraulic piston supports the counterweight at rest and raises and lowers the anvil slightly to clear small obstructions inside the unfinished pipe.

Since Fig. 4 shows that the anvil and horn just about fill the interior of the small pipes, the burners are mounted directly in front. Thus a certain area may be

FIG. 5. VARIOUS STYLES OF JOINTS

heated, and the carriage moved in, bringing the hot portion directly over the anvil and under the air hammer, swung from a beam directly above. Gas and air pipes hug the side of the horn closely, and project past the anvil, being stiff enough to form the overhanging support for the lower burner. The upper burner is shown in Fig. 4; it can be raised and lowered at will in order to prevent fouling the work and to judge of the temperature of the metal being heated.

Water gas is the fuel. As noted in a previous article,³ this gives a high temperature (1,900 deg. C.) and requires but $2\frac{1}{4}$ volumes of air for its perfect combustion. Thus it is relatively easy to get a quick and uniform mixture of air and gas without danger of forming heavy scale on the metal from the impingement of a poorly mixed stream of air and gas, portions of which would contain an excess of oxygen. All the gas lines are liberally supplied with traps or receivers, having explosion doors closed only with a rubber gasket. Each of the pipes leading to the burners is regulated by an ordinary one-way cock. These are adjusted by trial so that each pipe delivers the proper volume to its burner. Just beyond these cocks are gate valves, all operated simultaneously from the pulpit. A match thrown into the gas stream lights the burner for the first time; the incandescent brick is sufficient to ignite it thereafter.

Two men operate the machine; the welder, who controls the heat, the movement of the carriage, and the hammer. His assistant stands on the platform alongside the pipe, and with a clawbar, known as a "picker," rolls the pipe on its cradle as directed by the welder.

After adjusting the cradle rollers to the correct height, the carriage is moved forward over the horn, and any necessary blows struck alongside the seam to bend the flat edges⁴ so that one side is sure to lap slightly under the other. Then, when a portion of the seam at its mid-length is laid down to the satisfaction of the foreman, he heats an area of metal there to the correct temperature, lifting the upper burner from time to time to judge the heat. Turning off the gas, the carriage moves forward so the hot spot is between anvil and hammer, and the welding is rapidly done. A few light blows stick the metal together and eject considerable liquid cinder. Air from the cylinder is exhausted against the seam directly below the hammer, blowing away loosened scale before it is driven into the hot metal. As the metal cools somewhat, the force of the blow is increased, and the lap is reduced to the thickness of the plate, continuing the work down to dull red, through recalcence. A few strokes on either side give correct bend to the portions of the pipe which could not be pinched in the bending rolls, a few more drive the unwelded seam just alongside into its proper position, and an adjoining portion is ready for heat.

The burners are 20 in. long, and heat an area about 2 ft. long by 16 in. wide, requiring, in $\frac{3}{8}$ -in. plate, between 40 seconds and 1 minute to bring to temperature. Shifting the carriage ahead is quickly done, and in 3 or 4 seconds the weld is being hammered. Perhaps 100 blows suffice to weld and shape 12 to 14 in. of seam, so that a complete cycle requires approximately 3 minutes. Thus a 20-ft. pipe can be welded from end to end in about an hour.

SPECIFICATIONS FOR STEEL

Hammer welding is such a new departure that no definite requirements for the steel can yet be laid down. The American Society for Testing Materials⁵ has adopted the following tentative specifications for open-hearth steel plates for hammer welding; the physical and chemical properties of the steel used at Christy Park conform to these requirements:

Carbon.....	0.18 max. (no 25 per cent excess allowed)
Mn.....	0.30 to 0.60
P.....	0.04 max.
S.....	0.05 max.
Preferably free of Si, Ni, Cr. Maximum 0.05 for any one.	
Tensile strength: $\frac{3}{8}$ -in. plate or thinner.....	48,000 lb. per sq. in. or more
Thicker plate	45,000 lb. per sq. in. or more
Yield point, by drop of beam.....	0.5 tensile strength
Elongation in 8 in. (per cent).....	1,500,000 $\div$ tensile strength
(Less 1 per cent for each $\frac{1}{8}$ in. above $\frac{3}{8}$ in., with a minimum of 20 per cent).	
(Or less 2.5 per cent for each $\frac{1}{8}$ in. below $\frac{3}{8}$ in.).	
Cold bend.....	180 deg. flat upon itself without crack

Annealing is done in a regenerative furnace fired by producer gas. It is 10 ft. high by 12 ft. wide and 23 ft. long inside, with a row of vertical ports at each side. Its massive doors swing from the side, like garage doors, and are operated by hydraulic racks engaging pinions keyed to the hinge bolt.

The aim is to maintain this furnace at 1,650 deg. F. at all times. Bearing in mind the immense amount of reserve heat stored in the brickwork, it is apparent that it requires but a short time for a piece of ordinary thickness to acquire the annealing temperature, after which it is left to "soak" for 30 minutes. Thus each pipe is annealed singly immediately after welding is completed.

After this heat-treatment the doors are opened, the

³Plates up to 1 in. are welded without scarfing, by merely lapping over a distance approximately equal to one thickness and hammering down flat. Thicker plates are scarfing on their edges, bent to shape and welded.

⁴Proceedings, vol. 19, Part 1, p. 150. Specification A-78-21.

FIG. 6. MICROSTRUCTURE OF WELD IN UNSCARFED 3-IN. PLATE, PICKLED IN MIXED NITRIC AND SULPHURIC ACIDS

hot pipe is carried by crane immediately to the bending rolls. It requires but a few seconds to slip it around the top roll, adjust the end housing and lower rolls, when the whole pipe is rolled over and over to make sure the curvature is equal in all parts.

TESTS ON WELDS

The pipe is now ready for the finishing operations. First it is mounted in a large lathe, having a bed 42 ft. long to accommodate sections made of two lengths welded together with a circumferential seam. Two separate carriages may be set the proper distance apart so that tools cut off each end simultaneously. These crop ends have been used to determine the relative efficiency of the weld. In a recent test of this kind, two transverse test-pieces were cut from the extreme outer edge and two adjacent to these or a few inches farther in, one pair representing the body of the plate and one pair containing the weld. These pieces were straightened cold and milled on four sides to give a smooth surface for a distance of 9 in. and then pulled in a testing machine. On the average, the first ring cut showed the outside weld to have 95 per cent of the strength of the weld a few inches farther in.

Averaging 120 tests taken from pipe which passed inspection and whose fractures actually occurred at the weld gives the following results:

	Metal	Weld
Yield point.....	31,390 lb. per sq.in.	29,260 lb. per sq.in.
Ultimate strength.....	53,690 lb. per sq.in.	49,480 lb. per sq.in.
Efficiency of joint (based on tensile strength).....		92 per cent

One of the most interesting pieces of equipment is the flanging machine, used to expand, contract or flange—in fact, shape the end of the pipes into the many styles of joints which are specified for large conduits.

FIG. 7. MICROSTRUCTURE OF A GOOD WELD IN 30-IN. HAMMER-WELDED PIPE, MADE OF $\frac{1}{8}$ -IN. PLATE

One end of the machine is a lathe headstock movable along the bed to adjust itself to different lengths of pipe and also to permit the necessary travel during its operation. A pipe is attached to the faceplate of this headstock, while the weight is carried by a steady-rest or set of idling rollers placed somewhat beyond the center of gravity.

After the pipe is fixed in this manner, the headstock travels to the left, placing the open end of the pipe directly between water-gas burners, adjustable to clear the outside diameter of the pipe. Rotation of the pipe heats the end uniformly for the necessary distance, when the gas is turned off and further forward movement of the headstock brings the hot end up to the forming tool. This consists of a very substantial housing inclosing the necessary motive power, gearing and adjusting screws for an upper and lower forming roll and a pair of idlers to the sides. These rollers have been machined so their surfaces have the contour desired, and they pinch against the hot pipe, which meanwhile is being rotated by the headstock, forming the end to the correct shape.

Testing is done in a huge hydraulic testing machine with 45-ft. reach and 2,500 lb. per sq.in. capacity. Since it is customary to subject all pipe to a 50 per cent overload, and penstocks have been built up to 1,400 lb. per sq.in. working pressure, this machine is expected to fulfill requirements of even the heaviest pipe. In routine testing, the metal at 50 per cent overload is seldom stressed over 15,000 lb. per sq.in., well within the elastic limit of the material.

Any necessary rivet holes are then made by drilling or punching, and the pipe is subject to a rigid final inspection for shape and general condition. (It is necessary to make large wrought pipe closely conforming to a true circle along its length, in order to present the maximum resistance to collapse against external pressure—caused either by water or earth on the outside or by vacuum on the inside.) After painting with the specified protective coating the pipe is ready for shipment.

MICROSCOPY OF THE WELD

It is usually possible to determine the place where the joint has been made by a visual examination of a polished section after pickling with mixed nitric and sulphuric acid (Fig. 6), or after etching with a copper reagent. Deep etching digs a number of pits along the line of the weld where the acid attack is intensified. Microscopic examination usually reveals a small amount of oxide or slag inclusions along the line of the weld, although there will be stretches such as shown in Fig. 7, where none exist. Utter elimination of slag is perhaps impossible, but in a weld having 92 per cent strength they must be held to the extreme minimum. Sound welds properly annealed are characterized by the features shown in Fig. 7; a slight decarbonization in a very thin sheet, and a suggestion of columnar habit in the ferrite crystals occupying this region.

Determination of Volatile Matter in Coal

BY H. P. WILKINSON, JR.

THE value of the proximate analysis of bituminous coal to the engineer, coal dealer, power plant superintendent or coke plant superintendent is unquestioned. But there is always room for doubt as to how much can be predicted from this analysis concerning the behavior of the coal under consideration. This is especially true in the case of the coke-oven superintendent who expects the analysis to guide him in figuring the expected yield of his ovens. The ash and sulphur can be accurately determined by well-defined methods, and those tell him much about the quality of the coke. For the quantity, however, he must look to the volatile matter determination. At best this is an arbitrary figure, for regardless of the care exercised in taking, preparing and delivering the sample to the chemist it is practically impossible for two men working in different laboratories to obtain the same result. Assuming that the well-defined standard method is used, the results may be affected by the condition of the crucible, the style of cover used and the way it fits, the kind of burner and its condition, the kind of gas and the regulation of the flame, the possibility of mechanical losses due to the moisture passing off, and, greatest of all, the influence of the personal equation, which must be relatively great in any process having so many chances for error.

Considering it possible to overcome all these difficulties, the chemist's determination of volatile matter is still inadequate in predicting coke yield. It does not allow as much redeposition of carbon as occurs in the oven, due to the smallness of the sample and the size and shape of the space it occupies. Nor does it permit of any regulation of time or temperature, and these factors are both used in byproduct coke ovens, and have an influence on the amount of redeposited carbon, and thus on the amount of coke yielded.

The present outlook in the natural gas fields indicates a serious shortage, or even the complete exhaustion of the supply in a short time. This can be offset greatly by producing more coke-oven gas and there is a possibility that legislation may be enacted to restrict the burning of uncoked coal to those coals which are entirely unsuited for coking. This prospect for increasing activity in the manufacture of byproduct coke emphasizes the inadequacy of the present laboratory method for volatile matter, and creates a desire for a more reliable one—a method which will give data from which it is possible to predict the quantity and quality of coke yield. With a knowledge of this desire in mind, the writer conducted a series of experiments to evolve a method which will give a closer comparison between the volatile determination of the laboratory and the coking loss of the ovens.

METHOD USING LARGE SAMPLE AND ELECTRIC FURNACE

The method finally settled on as being most satisfactory involves the use of an electric furnace with variable temperature, and a 100-g. sample. The furnace is of the resistance type and consists of a vertical cylinder 2 in. in diameter and 4 in. long inside. (A slight taper facilitates the removal of the coke.) This sits on a silica base and the junction of the base and cylinder are ground to make a joint which is practically air tight. The top fits just as closely and a clamp is provided to insure against leaks. Through the top are

two holes, one into which a thermocouple is fitted and to the other is attached a tube for conducting the gases out of the laboratory.

In running a test the furnace is heated to the temperature of the ovens. The cover is then removed and the weighed 100-g. sample poured in quickly and the cover replaced and clamped. The coking is then allowed to proceed to completion, the time required being determined by the quality of the gas coming off through the outlet tube and varying with the temperature. The current is regulated during the coking to maintain uniform heating. When the coking is complete, the furnace is lifted from its base and the coke removed and quenched. It is then dried at 104 to 110 deg. C. and weighed, the weight in grams being the expected coke yield of the coal and the loss in weight the volatile matter.

DATA CHECK OPERATING RESULTS

In his experiments the writer used a number of coals, and the work was repeated often enough on the various samples to prove that he was duplicating his own results. The samples were ground to pass through a 40-mesh sieve. The data listed below were obtained from the "general mixture" from the coal-handling plant of the Toledo Furnace Co. This gives more satisfactory results for publication, since the coke produced in the laboratory can be compared with the coke produced in ovens charged with the same coal. The analyses of this by the standard method and by the writer's methods are:

	Standard Method Per Cent	Writer's Method Per Cent
Volatile matter.....	32.94	28.12
Fixed carbon.....	59.54	64.36
Ash.....	7.52	7.52
Fixed carbon and ash.....	67.06	71.88

The average yield in dry coke of the ovens per ton of dry coal was 72.10 per cent. Thus it is readily seen that 28.12 per cent is practically the true coking loss and therefore the valuable volatile figure. To show how nearly the method reproduces oven conditions the analyses of the two cokes are given:

	Oven Coke Per Cent	Laboratory Coke Per Cent
Volatile matter.....	1.76	1.90
Fixed carbon.....	88.52	88.25
Ash.....	9.72	9.85

The fact that this method gives a volatile figure that compares so favorably with the coking loss of the ovens is no doubt due to the size of the sample and the regulation of the temperature. The size of the sample permits the hot gases to redeposit approximately the same amount of carbon that the oven does. This, coupled with the regulation of the temperature, accounts for the quality of the coke.

The writer believes that this method will be a welcome innovation to routine control laboratories, because it gives uniformly reliable data from which actual coking yield can be predicted.

Toledo, Ohio.

Legal Notes

BY WELLINGTON GUSTIN

Tank Agitation Patent Held Invalid as Not Being Invention

In a suit brought by Niel D. Nielson and another against Libby, McNeill & Libby for infringement of patents, the Federal District Court for the Northern District of Illinois held invalid the Nielson patents 1,268,601, claims 6, 7, 12-15, and 1,268,602, considering the state of the prior art, and rendered a decree for defendants.

These patents were granted to Nielson June 4, 1918, for improvements in "agitating means," being a means for agitating the contents of a tank, and specifically a vertical, cylindrical tank, by means of an agitator, preferably in the form of a wheel, resembling an ordinary screw propeller such as is used in driving boats, arranged upon the inner end of a shaft extending through the side of the vessel near its bottom.

The first patent shows a tank having the central portion of its bottom convex; the second patent shows a tank or vat with a concave bottom. Both patents in suit show tanks provided with jackets into which a heating or cooling medium may be introduced to vary the temperature, but this feature was not mentioned in any of the claims in issue.

COURT QUOTES EXTENSIVELY FROM DECISION DECLARING MARCHAND PATENT INVALID

In holding the claims as numbered above of the first patent and all the claims of the second patent invalid as not being invention from the knowledge of the prior art, the court referred to the U. S. Supreme Court decision in the case of Marchand vs. Emken, 132 U. S., 195, wherein the Marchand patent was held invalid in the following language:

"The pretence that the complainant had discovered some occult and wonder-working power in the motion of a screw revolving in the bottom of a tub is not sustained by the proof. Whether the contents of the tub be oxygenated water, or soap, or lye, or tartaric acid, the action will be the same. That rotary, eddying motions in liquid will result from the revolving screw, that the liquid will rise highest at the periphery of the tub and thus have the tendency at the top to fall toward the center were well-understood operations of centrifugal force. As every device, apparatus, formula, law of nature, motion and ingredient adopted by the complainant was old, the patent must be held invalid, unless it can be said that giving to oxygenated water a well-known rotary motion springs 'from that intuitive faculty of the mind put forth in the search for new results or new methods, creating what had not before existed, or bringing to light what lay hidden from vision.' . . . No such faculty has been tasked in giving form to this patent. There is here no sufficient foundation upon which to rest a claim which, if construed as broadly as the complainant insists it should be, practically makes all pay tribute who stir the mixture in question by machinery, and by hand also, provided substantially the same movement can be produced by hand stirring, and this seems to be a disputed

question upon the proof. The complainant's claim to be enrolled upon the list of inventors is based upon propositions too theoretical and visionary for acceptance."

Laboratory Tests Cannot Outweigh the Test of Practical Use

A recent case in the Federal District Court for the Northern District of Illinois involved the Newberry patent, No. 851,347, for waterproofing portland cement by mixing therewith an insoluble salt of a fatty acid and no glycerine or other like water-attractive substance, and for the process for making the same. This same patent was involved in former litigation in McCormick Waterproofing Portland Cement Co. et al. vs. Medusa Concrete Waterproofing Co., 138 C. C. A., 14, where the Court of Appeals of the U. S. for the Seventh Circuit sustained a decree of the trial court holding the patent to be valid and infringed. In that case the court found that for forty years those skilled in the art had been aiming to overcome the attraction which concrete had for water. There it was said the capillarity of cement construction had been well known, and until Newberry came into the field nobody had offered anything like a practical solution of the difficulty.

PROOF THAT DEVICE DOES WORK KILLS EXPERT TESTIMONY THAT IT WILL NOT WORK

In this new attack upon the validity of this patent Dr. Gudeman was a new expert and it was attempted to show that laboratory tests determined that the Newberry process had no practical value. The court herein says that laboratory tests cannot turn the balance in the scale against practical use. The testimony of experts that a device will not work is of no value, if it does work. In the light of the practical use of this patent process the court assumed that Newberry discovered something worth while.

This action was brought by the Medusa Concrete Waterproofing Co. against the Ceresit Waterproofing Co. and others for infringement. The patent says to use an insoluble salt of a fatty acid and no glycerine or other like water-attractive substance, and it is mixed in small percentage with the cement. The defendant claimed that, because his product is in a paste, it does not come within the claims of the patent. Newberry recommends the drying of the product, although in the process of manufacture it is first in a wet or pasty shape of the defendant's product. But the patent says: "The resultant stearate of lime is to be dried, so that it is in the form of a dry powder."

MANNER OF MIXING THE ONLY DIFFERENCE IN THE PRODUCTS IN QUESTION

Newberry testified that his product was made and sold both in the paste and the powdered form, but the demand in the powdered form was greater because it was more convenient to mix with the cement and other materials when in the form of powder. Mr. Miner, an expert witness, testified that the only difference in the two products of the competing companies was the manner of mixing the compound with the cement on the job; the Medusa powder being mixed with the dry material and the water added to the mixture, whereas the Ceresit is mixed with the water and in that form added to the dry material.

The court said the infringement was clear, and a decree was granted the plaintiff.

Enamel-Lined Apparatus

Plant of the Elyria Enameled Products Co. at Elyria, Ohio, Engages in the Manufacture of Enameled Equipment for Service in Many Varieties of Plant Processing—Steel and Cast-Iron Containers—Burning Equipment—Composition and Properties of Enamels—Control and Management of Operations

By CHESTER H. JONES

WELL KNOWN to the industries producing a wide variety of substances for all markets where chemicals enter into the processes, ranging from the canning of fruits and vegetables, through acids and metallic compounds to dyestuffs and pharmaceuticals, the Elyria Enameled Products Co. at Elyria, Ohio, operates a plant of interest alike to chemical, ceramic and metallurgical engineers. The methods of manufacturing chemical plant equipment should be known, that the user may realize the limitations of mechanical design of ware and chemical resistance of enamel coatings. The modern methods of ceramic control in mixing ingredients and firing to the metal hold the attention of all ceramists. Metallurgists are interested in the best kind of metal for the purpose and in methods for making it better. Connecting the control of these operations in a scientific laboratory, the several branches are welded together to function through an ideal staff of technologists.

The photograph above, which was taken looking north, shows the entrance of the plant, with the laboratory building in the foreground and the office building on the left. Fig. 1 gives an idea of the building layout. Raw material in the form of steel plates grading in

thickness from $\frac{3}{8}$ in. to $\frac{1}{4}$ in. is unloaded from cars at the north end of the tank shop. The rough castings for enameled cast-iron vessels are shipped in from the Sterling Foundry Co., a subsidiary corporation at Wellington, Ohio, and are stored in the large stock room shown near the cast-iron machine shop. Storage is

FIG. 2. SHEARING OPERATION

provided for 100,000 gal. of oil to be used as fuel for the furnaces. Oxyacetylene supply is furnished from Linde oxygen drawn from cylinders and acetylene made in the gas house in special carbide outfits, both separately piped to the welding stations about the plant.

Steam is supplied from two Erie City hand-fired boilers. The engine room has a 100-kw. Westinghouse direct-current 220-volt generator direct-driven by an Erie City engine. One Ingersoll-Rand two-stage steam-driven compressor furnishes air at 90 lb. pressure for air hammers and enamel spraying outfits, while another produces 40 lb. air for the sand-blast plant. Feedwater for the boilers is heated in an open type Swartout feed-water heater.

The auxiliary mechanical department apart from the process operations is completed by an electrical shop

FIG. 1. BUILDING LAYOUT

FIG. 3. WELDING STEEL TANKS

and production or repair machine shop. This latter shop is equipped with lathes and drill presses for light machine and electrical repairs.

The steel plate enters the north end of the long tank shop (Fig. 1), where it is handled throughout the work by two overhead traveling cranes, one Toledo and one Morgan. The operations in this room consist of laying out, cutting and trimming, rolling and welding. Fig. 2 is a view of the shearing operation, where a bevel shear is trimming the plate to size. From this machine the plate continues to the Cleveland rolls, in the background of the same view, where the side of the circular container is formed to required radius. Bottoms for large tanks are kept in stock.

The welding of steel sections to form the rough completed tank is carried on at twenty-four stations, each of which is furnished with a No. 8 low-pressure torch. Operators use gloves and special goggles. Fig. 3 shows the work of making a joint at the junction of a convex bottom on a cylindrical tank. At the Columbus meeting of the American Ceramic Society Emerson P. Poste, director of research, presented a paper which shows the quality of steel obtained at these welds when the metal undergoes heat-treatment incidental to the firing of the enamel onto the ware, enhancing the quality and strength.

The surplus metal on the inside of the tank is ground off after welding by portable electric grinders made by the Heisey Wolff Co., of Cincinnati, and Van Dorn Electric Co., of Cleveland. The completely constructed tanks enter the sand-blast compartments.

The equipment for cleaning the surface to be enameled by sand blast consists of four Paxon units and according to the superintendent represents the "last word" in sand-blast machinery design. Coarse sand falls from steel storage hoppers into the sand-blast machines, where, mixing with the 90-lb. air supply, it is forced through armored hose to the operator's nozzle. Fig. 4 shows the operator applying the stream of sand to the inside of a tank. Protection is afforded him by a respirator and helmet which is fed with compressed air.

The sand from this operation falls through the steel grid floor and is elevated to a rotary screen separator. The head of one of the sand elevators with drive appears on the balcony in Fig. 4. The coarser particles fall back to storage for the next operation, while the fine dust is carried to four dust separators resembling baghouses. Circulation through this system is obtained by four Sturtevant exhausters driven by 20-hp. motors. The fines from the baghouses are rejected. All motors and switch boxes are totally inclosed to protect from dust. The steel containers are next transferred by industrial cars to the enameling department.

The mixing, smelting and grinding of the materials which go to make up the enamels for both the steel and cast-iron pieces is carried on in the mixing room and smelter, shown adjacent to the enameling department in Fig. 1. Typical formulas are given in the accompanying tables reprinted from the *Journal of the American Ceramic Society*, vol. 2, No. 12, December, 1919. The term "ground coat" in these tables refers to the first coat applied to the cleaned metal, while "cover coat" is applied over the ground coat to give finished appearance to the ware.

After mixing by hand or rotary mixer the raw batch is introduced into the oil-fired smelting furnace appearing in Fig. 5. This is essentially a reverberatory furnace and the operator is seen rabbling the mix. A rotating U. S. furnace is also employed for the same work. When the fusion is uniform, the molten glass is tapped and run into a vessel of cold water to produce the shattered frit. In the case of one type of cast-iron ground coat the smelting process is varied by placing the thoroughly mixed batch on a cast-iron tray, heating to a red heat and stirring at intervals. The resultant product from this sintering operation resembles pumice stone.

Wet grinding of the frit is in general used for sheet

Patterson and one 50-lb. Abbe pebble mills. Four of these mills are seen in Fig. 6.

Dry grinding simply consists of pulverizing the frit to a dust for direct application to the ware.

In wet grinding the mill additions consist of various materials introduced with the frit and water to hold the frit in suspension and form a creamy liquid suitable for spraying on the metal. According to R. R. Danielson, U. S. Bureau of Standards, in milling the ground coats it is general practice to add high-grade ball clay and water to the frit at the beginning of the operation and to add the borax in hot solution about one-half hour preceding the end of the operation. Magnesium carbonate and ball clay with small amounts (about 0.25 per cent) of an electrolyte such as magnesium sulphate or cobalt and nickel sulphates may be used for mill additions to cover coats. Typical mill additions are also shown in the tables.

FIG. 7. APPLYING ENAMEL TO STEEL

FIG. 6. GRINDING MILLS

While accurate data on the properties of enamels from the standpoint of chemical operations can be obtained only by submitting the particular process or essential conditions under which the enameled ware is to be used to the research laboratory, nevertheless the company makes three general grades some of the uses of which are outlined in the following paragraphs.

Enamel No. 11, which is applied to cast-iron ware, has been found to resist the action of inorganic acids such as hydrochloric, nitric, phosphoric, sulphuric, hydrobromic, hydriodic, aqua regia at any strengths and any mixtures of these. It is acted upon by hydrofluoric acid of any strength. It resists reactions of stannic chloride in hydrochloric acid, zinc chloride up to 300 deg. C., gaseous hydrochloric acid, aluminum chloride, bromine, chlorine, iodine (moist or dry), tungstic oxide precipitation by hydrochloric and nitric, sulphur dioxide, thorium nitrate in nitric acid, and manganese dioxide with hydrochloric acid. It may be

FIG. 8. STEEL ENAMEL FURNACES

used for all organic acids, acid chlorides and organic compounds, being particularly resistant to acetic vapors.

It is successful in vessels for heating magnesium hydroxide under pressure, for evaporating lime salts of sulphocarbates or boiling sodium carbonate, for ammonia and sodium or potassium salts of inorganic compounds, but is decomposed by caustic alkalis and is acted upon slightly by hot milk of lime. Sodium cyanide and similar salts are too alkaline and react with it. It is more resistant to alkalis than most enamels.

Enamel No. 20, which is applied to steel, has been used successfully for all strengths of organic acids (hot or cold), ammonium sulphate, acetic anhydride, acetic acid of all strengths, (but not the vapors), brine, moist chlorine, hydrochloric acid in alcohol, hydriodic acid, lactic acid of all strengths (hot or cold), hot phenol, tin chloride plus 1 per cent hydrochloric acid, zinc chloride solution, hot sulphur chloride, inorganic acids below 0.5 per cent strength cold, sulphuric acid above 50 per cent strength and mixed acids high in sulphuric acid, hot or cold. If the reagent is one which attacks iron severely, the enamel coat must be perfect, limiting the size to 600 gal. If there is no severe action on iron, any size up to 3,000 gal. can be had. The limiting size must be decided for each condition by itself. It is also used for hot carbonate, cold sodium hydroxide 10 per cent and hot ammonia.

Enamel No. 21, which is also applied to steel, is used for all conditions of milk, such as milk heating, holding, mixing, etc.; for oils, fats, alcoholic solutions of shellac, ammonia, aniline hydrochloride, acetic acid, storage cold; ammonium nitrate, bleach liquor, dry chlorine, dry hydrochloric acid gas, cold beverage sirups involving citric acid, grape juice, hydrogen peroxide,

FIG. 9. ASSEMBLING ENAMELED STEEL APPARATUS

tincture of iodine, making invert sugar, hot oil of peppermint, cold phenol, salicylic acid and hot acetic anhydride, dry sulphur dioxide, tannic acid, hot bromine, distilled water, and hot fuming sulphuric. The last has been handled more successfully by No. 21 than by other enamels. For perfect coats the sizes are limited to 1,000 gal. Otherwise any size up to 7,000 gal. can be obtained. Here, as with No. 20, the limiting size can be determined only after making a study of the case in hand.

Cast-iron units may be used with 75-lb. steam pressure in the jacket and up to 100 lb. inside the still. It has a coefficient of heat transmission about one-fourth that of copper. With steam, temperature up to 160 deg. C. in the jacket can be obtained. Up to 225 deg. C. an oil jacket can be used. Superheated steam at 315 deg. C. has been used on the small units. The enameled units have also been heated by a direct, well-spread flame up to temperatures of 300 deg. C., but such service is rather severe, limiting the life of the enamel.

Steel units are usually heated by means of a steam jacket, the 500-gal. sizes permitting 30-lb. pressure, the

FIG. 10. ENAMELED STEEL APPARATUS READY FOR INSPECTION AND TEST

large ones, such as 3,000 gal., being limited to 10-lb. pressure. The pressure within the tank may be one and a half times as great as that in the jacket. The coefficient of heat transmission is about one-third that of copper, using straw as a heating medium. Using oil in the jacket (which has been done up to 250 deg. C.), the coefficient drops to one-fifth that of copper.

The wet enamel from the mill room is stored in containers, whence it is drawn to the compressed air-spraying machines made by the De Vilbis, Toledo, Ohio, and the Paasche Co., Chicago, and located in the enameling room. Fig. 7 shows one of these outfits in operation on a steel tank, the spraying apparatus appearing on the left of the view. This is the usual method for coating the steel containers. They receive from three to five coats. Smaller pieces may be coated by dipping in a large tub of solution, or in cases where only one side is coated, the wet slip can be "slushed" over the surface held at such an angle as permits the excess to be drained off. Buffalo Forge Co. portable blowers are used for drying the successive coats of enamel as they are applied.

The steel enamel furnace room adjacent to the spraying department is equipped with one 6-ft., one 10-ft. and one 14-ft. furnaces, all constructed from firebrick

and of the open type with flame introduced from below. The largest furnace has hydraulic lifts for operating the doors, which part on a horizontal center line, saving time on the opening and closing movements. The burning temperature varies between 1,800 and 2,200 deg. F.

Fig. 8 is a view along the front of the three steel enamel furnaces, with the largest in the foreground. The charging machine, shown loaded with a piece ready to enter the large furnace, is manufactured by the Morgan Engineering Co., Alliance, Ohio. Each one of these machines is equipped with three electric motors, permitting movement of the piece in any one of three directions. The electrical controllers are operated in a pulpit to the rear of each machine.

One Morgan 5-ton overhead electric crane operates the length of the enameling department and along the front of the furnaces for moving the pieces about the enameling floor and placing them on the charging machines.

Oil is used for fuel in the steel-enameling furnaces and is burned by the General Combustion Co. oil-gas system. The blower equipment in this system consists of one 50/60-hp. electric-driven unit delivering 4,200

FIG. 11. ENAMELED STEEL APPARATUS UNDER TEST

cu.ft. of free air per minute and one 20-hp. electric unit with a 2,500-cu.ft. capacity, both pressures approximating 3 lb. Motors and blowers are manufactured by the General Electric Co. Brown Instrument Co. pyrometers record the burning chamber temperatures.

The first action on placing the coated ware in the furnace consists of dehydration of the clay and other mill additions which in drying have still retained moisture. The individual particles of the coat then melt and run together, giving an even distribution of glass over the whole surface. After the ground coat has been processed, the operation is repeated with the cover coats until the required surface is produced. All burning operations are carried on in an oxidizing atmosphere.

The steel assembly building, housing the assembling operations and shipping room, with the cast-iron machine shop at the east end, is 170 ft. long and has a Toledo electric crane with 36 ft. clearance operating its entire length. As the enamelled pieces are conveyed from the enamel department to the assembly department, those requiring steel jackets are built up by oxyacetylene welders near the point of entrance. Other parts, such as motors, agitators, brackets and pipe fittings, are attached until the required unit is finished and is then finally painted. Fig. 9 shows a series of operations of this nature. Fig. 10 is a view of com-

FIG. 12. CAST-IRON ENAMELING FURNACE

pleted units ready for inspection and test and Fig. 11 some of the units under test. The piece on the left of Fig. 11 is undergoing pressure test on the jacket.

The assembly machine shop adjoins the main building on the north and is furnished with lathes, drill presses and all other machine tools needed in the building up of the small parts for complete units. As noted, the cast-iron preparation room occupies the east end of the assembly building. Here all the rough castings are made ready for the enameling operations and later returned for additional machining required for assembly.

This department employs large boring mills, lathes and shapers for complete production. A small Paxon sand-blast equipment, similar to the units at the tank shop, operates in connection with this room and for use in cleaning surfaces to be enameled.

The cast-iron department enameling equipment, adjoining the machine shop, consists of one 4-ft. coal-fired muffle furnace and one 7-ft. Dutch oven furnace built by L. W. Manion, Canton, Ohio, using refractories from the Massillon Stone & Firebrick Co., Massillon, Ohio. Fig. 12 shows the front of the former with charging machine ready for operation.

The dry process of enameling is used largely for the cover coat on cast iron where the pulverized frit is dusted onto the piece and melted to an even surface. This gives the best enamel for resisting acids, being particularly high in silica. The absence of mill additions in the form of clay and electrolytes assures the intimate contact of particles of the dry frit to produce a true glass coating.

The dry powder is seen in a pan on the floor (Fig.

FIG. 13. FRONT OF CAST-IRON ENAMELING FURNACE WITH DREDGING APPARATUS IN OPERATION

12) ready for dusting onto the piece balanced above. Fig. 13 is the front of the 7-ft. furnace with the dredging apparatus in operation. The wet ground coat is first sprayed onto the cleaned surface in the usual manner, and after thorough drying the piece is placed in the muffle furnace and brought to a uniform temperature approaching a bright red.

Upon removal, the ware is not permitted to cool as in the case of steel enameling, but is immediately dusted with the dry frit powder. This is usually accomplished by placing powder in a sieve shaken by a compressed air or electrically operated vibrator held above the piece. The apparatus is called a "dredge" and is shown operating on the left in Fig. 13.

When a proper amount of frit has been applied to the revolving piece, it is run back into the furnace on

FIG. 14. ASSEMBLING ENAMELED CAST-IRON APPARATUS

forks and permitted to come to sufficient temperature to fuse the coat. The piece is again withdrawn and the operation is repeated, continuing with these cycles until the required thickness of glass is built up. The final firing is somewhat harder than the previous ones, resulting in a smooth surface and high gloss.

With the enameling operation completed, the thoroughly cooled ware is returned to the machine shop and assembly room, where it undergoes operations similar to the steel assembly. The complete apparatus may range from unjacketed open-top dishes to jacketed vacuum pans with agitator and other accessories. Fig. 14 shows some of the cast-iron units in process on the assembly floor.

It will be noted by reference to Fig. 1 that the shipping tracks are very well and simply located, entering the center of the plant in such a way as to discharge raw material and receive loaded cars from the shipping

FIG. 15. ENAMELED APPARATUS LOADED FOR SHIPMENT

FIG. 16. INTERIOR OF SUPERINTENDENT'S OFFICE

section in the assembly building. Fig. 15 shows a car at this location ready for shipment. Some of the smaller orders and express shipments are handled to railroad shipping platforms by Packard trucks.

The business control of the factory is handled from the factory manager's and superintendent's office, interior view of which appears in Fig. 16, and the department of mechanical design, employing two mechanical engineers and several draftsmen, as seen in Fig. 17, functions with the necessary aid of the research and control laboratories.

The laboratory building contains chemical engineering, metallurgical engineering and ceramic engineering departments, with analytical laboratory, chemical engineering laboratory, stock room and first aid room. The chemical engineering laboratory is equipped with cast-

FIG. 17. DRAFTING ROOM

iron and steel vacuum pans and condensers. The work here is chiefly concerned with the development of apparatus for adaptation to new lines of industry and investigation in connection with chemical inquiries.

The ceramic engineering department has to do with factory control and research on enamel. The apparatus for this work includes refractometer, petrographic microscope, Freas oven and Hoskins electric furnace. The furnace room has an experimental pot smelter, Abbe pebble mills, an experimental commercial furnace and other equipment for carrying out research on an industrial scale. The metallurgical engineering section deals largely with the quality of steel and cast iron used and the effect of various enameling processes upon them. A completely furnished microphotographic room operates in connection.

The laboratory work will be described in a subsequent issue of CHEMICAL & METALLURGICAL ENGINEERING.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Mono-azo Dyes.—Mono-azo dyes are obtained by coupling 4-nitraniline-2-sulphonamide (in which one or both hydrogen atoms of the sulphonamide group are replaced by alkyl, aryl or aralkyl) with a 2-naphthylamine sulphonic acid or a 2-amino-8-naphthol sulphonic acid, or a derivative thereof, in acid solution. As diazo components are mentioned 4-nitraniline-2-sulpho-ethylanilide, 4-nitraniline-2-sulphanilide, 4-nitraniline-2-sulphodiphenylamide, 4-nitraniline-2-sulphomethylanilide, 4-nitraniline-2-sulphomethylamide, 4-nitraniline-2-sulphomethyl-o-toluidide, 4-nitraniline-2-sulphopiperidide; as second components, 2-amino-8-naphthol-6-sulphonic acid, 2-methylamino-8-naphthol-6-sulphonic acid, 2-methylamino-8-naphthol-6-sulphonic acid, 2-naphthylamine-8-sulphonic acid, 2-naphthylamine-6:8-disulphonic acid, o-anisyl-2-naphthylamine-8-sulphonic acid. The products may be reduced with alkaline reducing agents. According to one example, diazotized 4-nitraniline-2-sulpho-ethylanilide is coupled with 2-amino-8-naphthol-6-sulphonic acid in glacial acetic acid solution yielding a navy-blue wool dye; in a second example the solution obtained by effecting the same combination in weak mineral acid solution is reduced by sodium sulphide giving a bluish wool dye. (Br. Pat. 164,218. Farbenfabriken vorm. F. Bayer & Co., Leverkusen, Germany. July 27, 1921.)

Dyes; Intermediate Products.—Indigoid vat dyes are obtained by condensing a halogenated isatin (in which the α -ketonic oxygen is replaced by a substituent such as halogen, sulphur, the anilido-group, etc.) with 1-oxy-6-naphthol ether or a halogen substitution product thereof, or with 1:6 dioxynaphthalene followed by alkylation or aralkylation; the products may be further halogenated. The dyestuffs obtained from 5:7 dichlorisatin α -chloride and 1-oxy-6-naphthol ether dyes cotton grayish blue to black shades, or, after chlorinating, black shades, from a hydrosulphite vat; that from dibrom- β -naphthisatin chloride and 1-oxy-6-naphthol ether dyes fast olive green shades; that from 1-chloro- or bromo-2:3-naphthisatin chloride and 1-oxy-6-naphthol ether dyes greenish gray; that from 5:7 dibromisatin- α -chloride and chloro-1-oxy-6-naphthol ether dyes grayish blue; 1-oxy-6-naphthol ethers are obtained by acetylating 1-amino-6-naphthol, alkylating the -OH group, removing the acetyl group and replacing the amino group by the hydroxy group in the usual manner. Chlor-1-oxy-6-naphthol ethers are obtained by chlorinating 1-oxy-6-naphthol ethers with SO_2Cl_2 in glacial acetic solution. Brom-1-oxy-6-naphthol ethers may be prepared by brominating the carbonate of 1-oxy-6-naphthol ether and then splitting off the carbonate group. (Br. Pat. 164,594. Farbenfabriken vorm. F. Bayer & Co., Leverkusen, Germany. Aug. 4, 1921.)

Alloys Containing Alkaline Earth Metals.—Alloys containing one or more alkaline earth metals are made by the reaction of an alloy containing an alkali metal or metals and one or more halogen salts of the alkaline earth metal or metals, mixed or not with other salts, the materials being maintained in a highly fluid state during the reaction. The salts used may include double or multiple salts, mixtures of different alkaline earth salts, salts of other metals which are capable of replacing the alkali metal in the alkali metal alloy such as aluminum, cadmium, copper, zinc, lead and bismuth, or salts of metals inert to the alkali metal in the alloy, such as sodium. If the metal which is to be alloyed with the alkaline earth metal does not alloy with an alkali metal, mechanical mixtures of the metals and alkali metal may be used. The salts may be present in large excess of the theoretical amount—for example 2 to 5 times—and may be heated considerably above their

melting point. In some cases the alkali-metal alloy or the molten salt or both may be maintained in motion during the reaction—for example by a counter-current method—or by causing the materials to impinge on each other, and the molten salt may be renewed during the process of substitution. The production of the following alloys is referred to: lead and calcium; lead and barium; lead, calcium and barium; lead, calcium and magnesium; lead, barium and magnesium; aluminum and magnesium; aluminum and beryllium; copper, calcium and boron; lead, manganese and barium; copper, aluminum and calcium. (Br. Pat. 164,608. G. J. Kroll, Luxemburg. Aug. 4, 1921.)

Phthalic Acid and Anhydride.—Phthalic acid or its anhydride are prepared by treating naphthalene vapor with air or other oxygen-containing gas in the presence of a small amount of vanadyl chloride at 300 to 650 deg. C. The mixture of naphthalene vapor, air and vanadyl chloride vapor is passed through a vessel or tube, empty or containing pumice, firebrick, kieselguhr, etc., and the products condensed in cooling chambers. In place of naphthalene other volatile hydrocarbons or their derivatives yielding phthalic acid on oxidation, such as α - or β -methyl-naphthalene, tetrahydronaphthalene, α -naphthol, or o-xylene, may be used. (Br. Pat. 164,785. British Dyestuffs Corporation, Ltd., London. A. G. Green, Hale, Cheshire, and J. W. Porter, Belfast. Aug. 10, 1921.)

Sodium Formate.—Sodium formate is produced by introducing carbon monoxide into water containing sodium sulphate and lime, the sodium sulphate being maintained at a concentration not greater than 7 per cent calculated as Na_2SO_4 . This concentration may be regulated by the presence of basic sodium calcium sulphate, $\text{Na}_2\text{Ca}_2(\text{SO}_4)_4(\text{OH})_2$, obtained by heating calcium or sodium hydroxide in water with sodium sulphate and calcium sulphate, or with substances containing or forming these compounds—e.g., calcium sodium sulphate or sodium chloride and calcium sulphate. Another method of maintaining the sodium sulphate concentration consists in adding sodium sulphate or calcium sodium sulphate or basic sodium calcium sulphate to replace the sulphate as it is consumed, excess of lime being either present in the reaction vessel or gradually added thereto. (Br. Pat. 165,163. M. Enverli, Oestrich, Rheingau, Germany. Aug. 17, 1921.)

Phenol-Aldehyde Resins.—Resins are obtained by condensing the *ar*-tetrahydronaphthol or mixture of *ar*-tetrahydronaphthols, obtained by alkali fusion from technical tetrahydronaphthalene sulphonic acid, with an aldehyde with or without the aid of a condensing agent; the resins may be rendered fast to light by treatment with acidylating, alkylating or aralkylating agents. According to examples, *ar*-tetrahydronaphthol and 30 per cent formaldehyde are boiled together, or heated in an autoclave to 110-115 deg. C.; or heated to 60-70 deg. C. in the presence of a little hydrochloric acid, ammonium chloride or potassium hydroxide, and the resulting viscous products washed and dried; these products are further treated with acetic anhydride, or with ethyl bromide and caustic potash. In other examples acetaldehyde is employed and the resins obtained heated with benzoic anhydride. For formaldehyde and acetaldehyde may be substituted their polymers or substances which form an aldehyde. The products are clear brittle masses, soluble in alcohol, benzene, dichlorobenzene, linseed oil and turpentine. (Br. Pat. 165,322. Akt. Ges. für Anilin-Fabrikation, Berlin. Aug. 17, 1921.)

Separating Nitrogen Oxides in a Mixture of Gases.—Nitrogen oxides are absorbed from dry gaseous mixtures by substances other than alumina which are capable of forming addition products at temperatures between 0 and -80 deg. C. and of liberating the nitrogen oxides again at a higher temperature, generally about 100 deg. C. The substances mentioned as suitable are ferric chloride, calcium, magnesium, copper, zinc and iron oxides, and certain aluminous products, such as dehydrated bauxite. The essential condition to be observed in order that these substances may absorb the nitrogen oxides is that the substances are obtained or dehydrated at low temperature. The heating to liberate the nitrogen oxides may be effected in a partial vacuum. (Br. Pat. 166,095; not yet accepted. Société Anonyme L'Azote Français. Paris. Aug. 31, 1921.)

Current Events

in the Chemical and Metallurgical Industries

More Plants Resuming Operations

Paper.—The Bryant Paper Co., specializing in the production of book papers, has resumed operations at a capacity basis, following a curtailment for about 12 months past. The plant will run on a 24-hour schedule, giving employment to about 1,200 operatives.

The American Strawboard Co., Noblesville, Ind., has resumed production with a full working force, and all departments are operating. The plant has been idle for some time past.

The Eastern Manufacturing Co., Bangor, Me., is now operating at full capacity in its pulp department, following production on about a 50 per cent basis for some months. The paper mills of the company are also running full.

Oil.—The Sinclair Oil Co., Muskogee, Okla., has resumed operations at its local refinery, following a shut-down for the past two months.

Copper.—The International Smelting Co. is arranging to blow in one reverberatory furnace at its Miami, Ariz., smelting plant on Nov. 20, following a suspension of operations for the past six months.

Sugar.—The Owosso Sugar Co., Owosso, Mich., has opened its plant at Lansing, Mich., giving employment to about 300 men.

The Mount Pleasant Sugar Co., Lansing, Mich., has commenced production at its mills with a working force of over 250 men.

Iron.—The Reading Iron Co. placed its Keystone blast furnace in operation on Nov. 1, following a suspension from Nov. 15, 1920.

The Carnegie Steel Co., Pittsburgh, Pa., has lighted another furnace at its New Castle, Pa., plant, increasing operations to about 75 per cent of normal. About 200 additional men will be employed at once.

The Bethlehem Steel Co., Bethlehem, Pa., has recently resumed operation of its Furnace D, making two units now in blast at the plant. The furnace has been banked since last April. Blast Furnace G at the mill is being relined.

The Donner Steel Co., Buffalo, N. Y., has blown in a second stack at its plant. The Rogers, Brown Co. has also placed a second furnace in blast at its mill.

In the Buffalo, N. Y., district, one blast furnace is now in operation at each of the plants of the Buffalo-Union Furnace Co., Wickwire-Spencer Steel Co. and the Lackawanna Steel Co.

Steel.—The Canonsburg Steel & Iron Co., Canonsburg, Va., has arranged for immediate resumption of operations at its local plant, following a shut-down since last spring. The company specializes in the manufacture of sheet steel, with plant giving employment to about 400 men.

The Atlantic Foundry Co., Akron, Ohio, is operating at full capacity in its steel department. The gray iron castings department is running at about one-half normal.

Enamelware.—The National Sanitary Manufacturing Co., Salem, Ohio, has increased production to about 60 per cent of normal, and plans to run full at an early date.

Alcohol.—The United States Industrial Alcohol Co., 27 William St., New York, is planning for the immediate reopening of another distillery at its New Orleans, La., plant, following a period of idleness. The company resumed at one of its New Orleans distilleries about the middle of October. The Baltimore, Md., plant of the company is running full.

Czechoslovakia Restricts Exports

The exportation from Czechoslovakia of sulphur, phosphorus, mercury and various chemicals, drugs and fertilizers, has been forbidden until further notice.

Chemists Clubs Exchange Greetings

During the recent visit of the British Society of Chemical Industry to the United States greetings were exchanged between the Chemical Industry Club, London, and the Chemists' Club, New York. The following message was conveyed to the Chemists' Club by Captain C. J. Goodwin on behalf of the Chemical Industry Club:

Aug. 10, 1921.

To the Chemists' Club, New York:

The chairman and the committee of the Chemical Industry Club, London, desire on behalf of the members, on the occasion of the visit to the United States of representatives of the Society of Chemical Industry, to send their very cordial greetings to their colleagues of the Chemists' Club of New York.

Both institutions are united in a desire to cultivate and provide for the social side of chemical industry and chemical science, and by opening their doors to visiting members of either club have already done something and may yet do more to promote the acquaintance and consolidate the friendship of the chemists of both nations.

At the present moment the greetings we send through Captain Goodwin have more than a purely personal and domestic interest. They are an indication of the sincere desire on this side for increasing friendship and good understanding between Great Britain and the United States, as a guarantee not only of the progress of the two great English-speaking nations but of the peace and well-being of the world.

This visit takes place at a time when all the influences that make for international friendship need to be cultivated, and among the most stable bonds of unity is the common service of mankind through scientific research and the application of its results to industry. On this basis the scientists, and especially the chemists, of your nation and ours, may find common ground in their sympathies, aims and work. Both can gain nothing but good for a better acquaintance and closer association with each other, and in sending these words we desire you to accept them, not only as a courtesy, but as representing our sincere desire for ever increasing friendship and co-operation between Great Britain and the United States.

(Signed) H. Edwin Coley,
Hon. Sec.

The following cordial response was made to the Hon. Sec. of the Chemical Industry Club, by Thomas R. Duggan, trustee of the Chemists' Club:

Sept. 15, 1921.

Dear Mr. Coley: Your letter of the 10th of August was duly conveyed to the Chemists' Club through the kind offices of C. J. Goodwin. . . . It is needless for me to say that letters of this sort passing between the various countries where English is spoken can only do good, more especially when those countries are knitted together in one common cause; that is, the uplifting and the spreading of science throughout the English speaking races. . . . It is my pleasure to pass to you the friendly feeling which the whole of the Chemists' Club feels toward the Chemical Industry Club.

On behalf of the trustees and officials of the Chemists' Club I have to thank you for your kind greetings and also to thank Mr. Goodwin, who so kindly conveyed by word of mouth the feelings that have existed between the two Clubs and which he hoped and we also hope will exist for many years to come.

(Signed) Thomas R. Duggan,
Trustee.

Bauxite Deposits in Australia

The Australian bauxite deposits are being thoroughly investigated with a view to the establishment of an aluminum industry in that commonwealth.

Program, Baltimore Meeting, American Institute of Chemical Engineers

The fourteenth annual meeting of the American Institute of Chemical Engineers will be held in Baltimore, Dec. 6 to 9, with headquarters at the Emerson Hotel. In addition to the technical program and plant visits noted below, excellent arrangements have been made for the entertainment of the ladies.

TUESDAY, DEC. 6.

Meeting at Emerson Hotel.

9 a.m.—Registration.

9:15 a.m.—Business session. Canvass of ballots for officers.

Reports of officers and council. Reports of committees.

10:30 a.m.—Reading of papers.

Symposium on Chemical Engineering and National Defense.

Address, President David Wesson.

"Chemical Engineering and National Defense," M. C. Whitaker.

"Explosives and Fertilizers," Alfred H. White.

12:10 p.m.—Luncheon at Emerson Hotel.

1:15 p.m.—Excursion to Curtis Bay Industries: The American Refractories Co.; the Davison Chemical Co. and Silica Gel Corporation; the U. S. Industrial Alcohol Co.

8:15 p.m.—"Get Together" at Maryland Country Club.

WEDNESDAY, DEC. 7.

9:15 a.m.—Leave for Edgewood Arsenal. Note: This visit is open to U.S.A. citizens only.

12:30 p.m.—Luncheon at Edgewood. A complete inspection and tour of the arsenal will be made during the morning and afternoon. Brigadier General Amos A. Fries will give a short address in connection with the inspection of the arsenal on the subject of chemical warfare.

8:15 p.m.—Theater party. Invitation extended to the ladies and the institute by the local committee and the local chemical industry.

THURSDAY, DEC. 8.

9:15 a.m.—Meeting at Emerson Hotel. Reading of papers.

Symposium on Chemical Engineering and National Defense, continued.

"The Future Warfare," Raymond F. Bacon.

"Chemistry and the Next War," Maximilian Toch.

"Fundamental Research in Conservation and Defense," Harrison E. Howe.

"The Chlorine Industry as an Essential Factor in Our National Defense," Benjamin T. Brooks.

12 p.m.—Visit to Annapolis.

1:30 p.m.—Luncheon at Carvel Hall, Annapolis.

8 p.m.—Meeting at the Johns Hopkins University at Homewood.

"The Oxidation of Carbon Monoxide to Dioxide at Room Temperatures by a Catalyst," Prof. J. C. W. Frazer.

"Ultra Violet Light," Prof. R. W. Wood.

FRIDAY, DEC. 9.

Meeting at Emerson Hotel.

9:15 a.m.—Business session.

10:15 a.m.—Reading of papers.

"Some Aspects of the Lime Industry," Major Edward Holmes.

Paper by Prof. Cavalier of France.

"Glass as a Material for Chemical Use," A. E. Marshall.

12 p.m.—Luncheon at Emerson Hotel.

1:15 p.m.—Visit to Baltimore industries: Practically all of the Baltimore plants engaged in chemical and allied lines of manufacture have offered to throw their plants open to the institute. Lists will be available at the registration desk, and arrangements made to suit the individual preferences of members.

7 p.m.—Subscription dinner at Emerson Hotel. \$3 per cover.

SATURDAY, DEC. 10.

Optional visits at Baltimore and Washington.

Industrial Cost Association Holds Second Conference in Pittsburgh

With headquarters at the William Penn Hotel in Pittsburgh, Pa., the Industrial Cost Association held its second National Industrial Cost Conference on Nov. 2, 3 and 4. The meeting was well attended and the members departed with the comfortable feeling of having accomplished a creditable amount of useful work.

After registration and the other formalities had been gone through on Wednesday morning, the president, Horace S. Beck, controller S. K. F. Industries, Inc., New York, called the first session to order and made a short address. He commented on the work done by the association during its first year of existence and commended the officers and members on what had been accomplished. He also stated that it was planned for the coming year to have presented at each local section meeting a paper prepared under the direction of the executive committee of the association, in order to assist in the work of the sections.

The afternoon session was opened by an address of welcome from Mayor Babcock, of Pittsburgh. The conference then listened to a paper read by S. B. Taylor, general manager, S. K. F. Industries, Inc., New York, on "What the Sales Manager Should Have From the Accounting Department." Mr. Taylor enumerated various details and figures that must be supplied by the accounting department. He laid particular stress on the need for cordial co-operation between the members of the accounting department and the members of the sales department. The plea for co-operation was strongly indorsed in the discussion which followed his paper.

E. C. Grimley, Victor Talking Machine Co., Camden, N. J., then discussed the matter of taking inventories, contrasting the time required and the benefits accomplished from the old-fashioned annual or semi-annual inventory which necessitated shutting down the plant, and the more modern perpetual inventory as practiced in most progressive plants.

In the evening papers were read by F. S. Willett, controller, Dodge Manufacturing Co., Mishawaka, Ind., on "Responsibility of the Controller or Accountant in Times of Business Depression," and by T. W. Dinlocker and A. W. Wainwright, both of S. K. F., on "Idleness and Its Relation to Industry in Retrospect."

The Thursday morning session was opened by an interesting paper by Addison Boren, Yale & Towne Manufacturing Co., Stamford, Conn., on "Terminology." After luncheon at the Heinz plant the delegates listened to addresses by J. B. Ayres, sanitation and safety engineer, and Major William Hogg, assistant to the vice-president, National Tube Co., Pittsburgh. These gentlemen described some of the safety and sanitation work of the United States Steel Corporation and outlined the actual savings in dollars and cents possible to attain.

At the meeting of Friday morning, J. M. Howell, General Electric Co., Schenectady, N. Y., read a paper on "How Can a Cost System, Although Efficient, Demoralize an Organization?" In his paper he criticised the ready-made cost system as applied by certain consulting accountants and told of the harm it could do when local conditions were not taken into consideration.

U. S. Potters' Convention

At a special meeting of the executive committee of the United States Potters' Association at East Liverpool, Ohio, Oct. 20, it was voted to hold the annual convention of the organization at Washington, D. C., during the first week in December, with a three-day session.

German Ammonia Output to Be Marketed by Fertilizer Syndicate

Ninety-six per cent of the German output of ammonia will be marketed by the Fertilizer Syndicate, reports a cable from Berlin, but it is not expected that the syndicate will be able to place it on the market before June, owing to the present scarcity of raw material caused by the disaster at Oppau.

Atmospheric Pollution Committee, A.I.C.E.

A committee has been appointed by the American Institute of Chemical Engineers to study conditions in chemical engineering processes which result in the production of gases which pollute the atmosphere. It is the purpose of the committee to study the non-injurious effluent SO_2 gas concentrations rather than the result of processes producing said gas. The work of the committee will be carried on through investigations, publications and discussions of the results obtained. The committee will welcome any information or facts bearing on the question of atmospheric pollution in any of these phases relative to the chemical manufacturing industry either through members of the institute or others.

The membership of the committee is as follows: James R. Withrow, chairman, professor of industrial chemistry, Ohio State University, Columbus, Ohio; Charles Baskerville, professor of chemistry, College of the City of New York, New York, N. Y.; Arthur B. Conner, chemical engineer, Detroit Chemical Works, Detroit, Mich.; Andrew M. Fairlie, consulting chemical engineer, Atlanta, Ga.; Henry Howard, Grasselli Chemical Co., Cleveland, Ohio; Cyril B. Clark, chemical engineer, General Chemical Co., 25 Broad St., New York, N. Y.; Albert E. Marshall, works manager, Davison Chemical Co., Curtis Bay, Md.; Arthur M. Comey, E. I. du Pont de Nemours & Co., Wilmington, Del.

American Association of Textile Chemists and Colorists

Formal organization of the American Association of Textile Chemists and Colorists was completed at a meeting held in the Engineers' Club, Boston, Nov. 3.

Prof. Louis A. Olney, of the Lowell Textile School, was elected president. Other officers are: William D. Livermore, chief chemist of the American Woolen Co., Lawrence, Mass., and William H. Cady, chief chemist of the United States Finishing Co. of Providence, R. I., vice-presidents; Walter E. Hadley, chief chemist of the Clark Thread Co., Newark, N. J., secretary; Winthrop C. Durfee, consulting and manufacturing chemist, of Boston, treasurer, and the following executive council, who will govern the new association: George A. Moran, chief chemist of the Pacific Mills, Lawrence, Mass.; Walter M. Scott, chief chemist of Cheney Bros., South Manchester, Conn.; A. E. Hirst, chief chemist and assistant superintendent, American Printing Co., Fall River; Elmer C. Bertolet, professor of textile chemistry, Philadelphia Textile School; James L. Amsden, chemist of the Rockland Finishing Co., Haverstraw, N. Y., and W. K. Robbins, of the Amoskeag Manufacturing Co., Manchester, N. H.

The objects of the organization are:

To promote the technical interest of its members in the properties and application of dyes and the processes of scouring, bleaching and finishing.

To develop a closer relationship between theory and practice in the application of dyes and other chemicals used in the textile industry.

To serve the textile and color industries by developing standard methods of testing dyes and analyzing textile materials in general and of standardizing systems for these tests and recording their results.

To encourage research work along textile chemical lines.

To encourage and supervise the establishment of a complete textile chemical library.

Two classes of membership have been provided for—active and junior. Active members must be at least twenty-six years of age and actively engaged as textile chemists or in some branch of the application of dyes. Students and apprentices may become junior members.

Weeks and Ford to Confer

The Secretary of War and Henry Ford will "get down to figures," as the Secretary of War puts it, on Muscle Shoals at a conference slated for Nov. 18 in Washington. Since the Army engineers and Mr. Ford's engineers have reached an understanding as to the engineering phases of Mr. Ford's offer, all that remains to do is the bargaining.

Emergency Tariff Act Extended

The Senate on Nov. 8 voted to extend the emergency tariff act, which provides among other things for the control of certain dye and chemical imports, until the permanent tariff bill will have become a law. The consideration of the extension, to which there was no real objection, nevertheless gave an opportunity for further discussion on the floor of the Senate of the dye embargo. Senator Smoot of Utah, in urging that the act be extended, declared that no one is more opposed to a permanent dye embargo than himself, but he contended that as long as there is not enough protection under the Underwood act, which he declared all would admit is not sufficient, he urged that the present method of handling dye imports be continued until the permanent tariff becomes a law.

"For months past," said Senator Smoot, "I have been studying the question of German manufacture of dyes. I have collected current prices in Germany, Switzerland, England and in other countries. I also have collected the prices of American products. I am quite certain that we can protect the industry without imposing an embargo."

The bill as it passed the House was extended until Feb. 1. This was amended by the Senate so as to continue the emergency tariff in force "until otherwise provided by law." The discussion of the amendment revealed that the passage of the tariff bill may be delayed much longer than had been expected. One Senator predicted that it would not be enacted until summer.

Senator Pomerene of Ohio declared that "the dye-makers have got control of chemists, at least persuasively so, and chemists have come to the conclusion that they are not able to do anything in this country without an embargo." He expressed curiosity as to the source of the chemists' inspiration. He said the word "embargo" was hated in America more than any other one word in the language. Since Senator Pomerene's position is typical of that of a considerable number of Senators, his remarks are of interest as they outline the reasoning of those who are opposed to the granting of that measure of protection. Among other things he said:

"It is little short of a crime to place the woolen, the cotton, the silk and the paint industries of this country in a position where they must buy all of their supplies at home. Many domestic dyes are the equivalent of those produced elsewhere, but many are not good. The dye-makers in their unadulterated selfishness would place all of those great industries entirely at the mercy of themselves. I do not think it makes much difference to those industries whether they are dominated by a German dye trust or an American dye trust.

"I do not think the dye-makers are in danger of destruction by competition from abroad. During the past year only \$5,000,000 worth of dyes was brought into this country, while nearly \$30,000,000 worth was shipped out. American dyes were shipped abroad and were sold in other countries in competition with German dyes."

Senator Pomerene read from correspondence with H. W. Harris of Alliance, Ohio, who served more than 25 years in the consular service. In that correspondence he pointed out that American textiles are being crowded out of foreign markets because of the inferiority of the dyes used.

Chemistry Building Dedicated at Dartmouth

The Steele Chemistry Building at Dartmouth College, Hanover, N. H., the latest addition to the institutional buildings, was dedicated on Oct. 29 in the presence of Governor A. O. Brown of New Hampshire, former Governor Samuel E. Pingree of Vermont, Dean Henry P. Talbot of the Massachusetts Institute of Technology and Dr. William H. Nichols. The structure was erected through a bequest of \$250,000 from the late Sanford H. Steele, an alumnus of Dartmouth.

Early Vote on Patent Office Salary Bill

Early consideration of the bill providing for increases in salaries and certain reorganization in the Patent Office is assured. A majority of the Committee on Rules is understood to have agreed to vote for a special rule which will bring that bill before the House for a final vote soon.

Personal

CHARLES E. HEILMAN, chief metallurgist of the General Motors Laboratory, spoke on Nov. 10 on "Correlation Between the Testing of Automotive Parts, With Their Heat-Treatment and Service," at the Detroit Chapter of the American Society for Steel Treating.

HARRISON E. HOWE has been elected editor of the *Journal of Industrial and Engineering Chemistry* and director of the American Chemical Society News Service, to succeed Dr. Charles H. Herty. Dr. Howe has had a wide and varied experience in chemical industry. After completion of post-graduate work at the University of Michigan, Dr. Howe began his commercial career by accepting a position in the beet-sugar industry. Later he became chief chemist of the refinery. In 1904 Dr. Howe joined the staff of the Bausch & Lomb Optical Co. At first he was attached to that concern's Chicago office and traveled widely in that region in an effort to interest schools and others to use more scientific apparatus. Later he became branch manager of the Chicago office. After a time he was transferred to Rochester, N. Y., to edit the publications and books of instruction of the company. From that post he was promoted to the position of chief chemist. In 1916 Dr. Howe was employed by Arthur D. Little, Inc., as a chemical engineer and as manager of its commercial department. Later he was transferred to Montreal as assistant to the president. While in Canada he was engaged in the important survey of the dominion's natural resources made for the Canadian Pacific Railway. During the war Dr. Howe went to Washington as a consulting chemist in the Nitrate Division of the Ordnance Department of the Army. After the Armistice he returned to the Little company for a short period and on June 1, 1919, joined the staff of the National Research Council as the chief of its Division of Research Extension. He has been a member of the Council of the American Chemical Society since 1912 and is now a councilor-at-large. He is a member of the committee on national policy and was formerly chairman of the Division of Industrial and Engineering Chemistry of the society. He was instrumental in forming the society's Rochester section. He is the representative of the American Institute of Chemical Engineers on the board of American Engineering Council.

Dr. ERNEST FOX NICHOLS, inaugurated last spring as president of the Massachusetts Institute of Technology, was prevented by illness from assuming his duties at the opening of the academic year. He is expected to return about Jan. 1. His ill health was brought about by overwork previous to his election to the presidency. Meanwhile the institute will be governed by an administrative committee.

Dr. WILLIAM H. NICHOLS addressed the Rochester Chamber of Commerce at its midweek luncheon, Nov. 2.

Prof. LOUIS A. OLNEY, of the Lowell Textile School, has been elected president of the newly organized American Association of Textile Chemists and Colorists.

LATHROP E. ROBERTS, of Northampton, Mass., has been added to the Bureau of Mines staff at Berkeley, Cal., to take care of the additional work in physical chemistry. Mr. Roberts will be in immediate charge of the physical chemistry work at Berkeley, Cal. He is a graduate of the University of Chicago and has done extensive work on the theory of orientation of molecules. He was instructor in chemistry for two years at the University of Pittsburgh and for the past eighteen months has been in charge of the research laboratory of the American Writing Paper Co., Holyoke, Mass.

ERNEST T. TRIGG, Philadelphia, Pa., an official of John Lucas & Co., manufacturers of paints and varnish, has been appointed chairman of the recently established industrial relations committee of the Chamber of Commerce of the United States, Washington, D. C.

Dr. LANSING S. WELLS, until recently research chemist with The Barrett Co., Frankford, Philadelphia, Pa., has

accepted an appointment as assistant professor of organic and physical chemistry, Montana State College, Bozeman.

SANFORD L. WILLIS, of the Corning Glass Works, sailed for Glasgow, Scotland, on Nov. 12. During the next four months Mr. Willis intends to visit the principal industrial centers of Europe, where his work will be concerned chiefly with an investigation of the foreign patents and manufacturing rights for Pyrex glassware.

JOHN F. WOOD, East Liverpool, Ohio, heretofore secretary-treasurer of the National Brotherhood of Operative Potters, has been elected president to succeed Edward Menge, who resigned recently on account of ill health.

Obituary

GEORGE L. GOULD, a prominent paint manufacturer of Boston and a former president of the National Paint, Oil and Varnish Association, died at his home in Malden, Mass., on Oct. 30. He was born in Woburn, Mass., on Feb. 6, 1852. Mr. Gould started in the paint business in 1867 and for more than thirty years was president of the Gould & Cutler Corporation of Boston. He was also a director of Benjamin Moore & Co., Brooklyn, and president of C. J. Prince Co. of Boston. Mr. Gould was the author, in 1914, of a historical sketch of the paint, oil and related industries of Boston, and in many other ways had contributed to the development of these industries.

GEORGE H. STEVENSON, of Maplewood, N. J., who for the past eighteen years had been connected with the General Chemical Co. of New York, died on Oct. 31 at the age of fifty-four years.

DIMITRI KONSTANTINOVITCH TSCHERNOFF was born in Petrograd, Russia, on Nov. 1, 1839, and died on Jan. 2, 1921.

He obtained his early education in the Russian Gymnasium (corresponding to the American high school), after which he entered the Technologic Institute. On graduation from this institute in 1858 he was engaged as a professor of geometry and algebra and later as a librarian and superintendent of the museum in the same institute. At the same time he attended lectures in the mathematical physics section at the University of Petrograd. In 1866 Tschernoff left the institute and entered the employ of the Obouchoff steel plant (founded three years previously), where steel guns were manufactured. It was in this period of his life that the most important and pioneer work was done by him on the heat-treatment of steel, its crystallization and metallography.

In 1880 he left the Obouchoff plant and went to the south of European Russia, where he discovered and developed some rock salt mines. This enterprise brought him a rather large fortune. Tschernoff returned to Petrograd in 1884 and held several prominent positions in government departments. Five years later he became professor of metallurgy in the Michael Artillery Academy, in which capacity he remained up to the time of the Russian revolution. During that autumn he was spending his vacation as usual in city of Yalta (Crimea). The events of the Russian revolution progressed very rapidly, so that Prof. Tschernoff, with his wife and daughter, was compelled to stay in Yalta without being provided for the winter season. Suffering from hunger and the lack of sufficient clothing, and deprived of his books and laboratory, Tschernoff nevertheless continued his work as well as he could, and gave a number of lectures on steel before classes in the local Polytechnic Institute. At the same time he worked on some mathematical problems, but his physique broke down through long-continued undernourishment and on Jan. 2, 1921, he passed away.

His works in metallurgy are very well known to the students of that science and a good abstract of his most important papers was published in *Revue de Métallurgie* in 1915 (pp. 829-882) in commemoration of his seventy-fifth birthday. It may be pointed out here that he was a man of remarkable versatility. Perhaps next to metallurgy his interest lay in such widely diversified branches of knowl-

DIMITRI KONSTANTINOVITCH TSCHERNOFF

edge as astronomy, aviation and botany. Photography also claimed a large part of his interest and attention, and his favorite photographs were those he took of the frost on the windows of his conservatory. Some of the photographs in this wonderful collection were used during his lectures on the crystallization of steel. Among other things in which he evinced great interest was the construction of the violin and the violoncello, of which he was very fond. He advanced a theory that the fibers of the wooden boards comprising the violin box should be arranged in a certain manner in order to obtain the best tonal value. Violins which he constructed in accordance with this theory were found to be of excellent tone and enjoyed considerable popularity among Russian musicians.

In his house, surrounded by a beautiful park and located in the remote residential part of Petrograd, Tschernoff led a very simple and modest life, being entirely devoted to his family and his works. In spite of very poor eyesight, which he overstrained while making his observations on the bessemer process, he was a very hard reader. On the large table in his office one could notice a great number of the latest editions and magazines on various subjects and written in different languages. He was absorbed from very early in the morning and up to late in the evening in his endless study, taking a respite for a short time by working in his garden or in his small machine shop. He permitted himself a good rest during only two days in each month. Every other Sunday of the month his house was opened to a company of his own friends, and his family acquaintances. In the evenings of these Sundays Tschernoff usually placed chess, to which, like his old friend Mendeléeff, he was ardently devoted.

As in the case of a number of Russian scientists, the horrors of the revolution compelled him to live the last three years of his life under very miserable conditions, which broke his body but not his spirit, for according to a letter from his younger son he continued his study and work up to the last moments of his life. So far as is known at the present time, his widow, Mme. A. N. Tschernoff, and one of their daughters live in Petrograd (Sergievskaja St. No. 1, Apt. 1) under miserable conditions.

A. I. KRYNITZKY.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Nov. 14, 1921.

The chemical market during the past week was not very brisk, owing to the holiday spirit, and trading was confined to small quantities. Exporters report a steady demand for the more important commodities and the market seems to be in good shape on these products. Consumers have been purchasing caustic soda in carload lots at lower figures, but lesser quantities are still commanding top-notch prices. Cream of tartar has firmed up considerably and recent quotations have been well sustained. Yellow prussiate of soda has eased up after a period of extreme activity and goods are now available in several additional quarters. Caustic potash opened rather dull, but finished very strong, with buyers paying particular attention to the available supplies of spot material. Yellow prussiate of potash was firmer, with supplies limited and the call decidedly better. There was also an increased export demand from the Far East for formaldehyde. In general, the market had every appearance of stability. Prices all around show signs of remaining steady and resale surplus stocks are diminishing in noticeable volume.

CHEMICALS

Recent importations of powdered *chlorate of potash* have had a discouraging effect on trading and the market remained dormant, with prices a trifle easier. Sales were quoted down to 6c. per lb. at the close of the week. The general tone of the market was rather weak. The crystal variety, however, remained firm at 8c. per lb. Small-lot trading was about the only thing that featured the market on *bichromate of potash*, with prices hovering around 11@11½c. per lb. for spot material. Consumers have shown some interest in this item, but business still retains its conservative form of trading. Firmness in *yellow prussiate of potash* was characteristic of the market and prices closed somewhat higher at 21c. per lb. Limited stocks among leading holders have caused this strength in the local market. Trading in *bichromate of soda* was fairly active and prices remained unchanged at 8½@8¼c. per lb. The tendency of the *caustic soda* market was toward lower levels, and sales at the close were reported down to \$4 per 100 lb. for carload quantities. Lesser lots sold at \$4.10@ \$4.20. Leading producers of prime *acetate of soda* are finding a steady outlet among consumers at 4@4¼c. per lb. Dealers in the resale market are offering odd lots at 4c. per lb., with a probability of shading on round-lot actual business. There was a relaxation noted in the market on *yellow prussiate of soda* and prices eased off slightly to 14½c. per lb. The demand was rather quiet and imported shipments were noted in several new directions. Business in *oxalic acid* was reported more active since the recent sharp slump and orders were placed in better volume at 12½c. per lb. The market ranged up to 14c. per lb. according to quantity and seller. Prime *Glauber's salt* is offered by producers at \$1.50 per 100 lb. packed in single bags for carload quantities and up to 2c. per 100 lb. for smaller lots. The inquiry on this product seems to be fairly active, with consumers in several instances looking for contract figures. Manufacturers of *zinc carbonate* report sales to the consuming trade at 16c. per lb. Second-hand merchants quote the market about 2c. per lb. lower on firm business. The demand for the chemical has not been so very bright and most of the passing transactions have been for small quantities. The market on *soda ash* is reported steady, although business during the past week has not come up to expectations. Domestic ash remains practically unchanged at \$2.10 per 100 lb. for large quantities and up to \$2.50 for proportionately smaller lots. Foreign material is available at \$1.95@\$2 per 100 lb. A noteworthy improvement is reported in *formaldehyde* on the spot market and prices remained quite firm. The domestic demand has become more active and export business has shown a decided

improvement, especially to Japan. Prices remained at 11@11½c. per lb. for quantity orders. Producers of *silicate of soda* quote carlots of the 60 deg. at \$2.30 per 100 lb., with less than carload quantities at 3c. per lb. The 40 deg. test is offered at 95c. per 100 lb. for large-quantity orders. Business seems to be running along in fair fashion with the inquiry coming from various consuming channels. Trading in *nitrite of soda* was rather limited and the market closed at 7@7½c. per lb. Buyers did not seem very anxious to buy at the quoted figures and purchased only small quantities for immediate necessities.

COAL-TAR PRODUCTS

The coal-tar products market displayed practically the same tendency as the heavy chemical market. Holiday periods had somewhat of a bad effect on trading and stability of prices, but in general the entire list showed signs of firmness. Inquiries were more numerous and leading producers were optimistic about the outlook for the near future. The leading feature of the market was the increased demand for phenol, and factors are predicting higher prices for this product in the very near future. Naphthalene flakes have also attracted considerable attention in the market and holders are keeping their spot stocks well in hand for the expected rise in price. Imported arrivals have not been as plentiful as a few months ago, owing to the recent additional tax of 15 per cent ad valorem. Dimethylaniline attributed considerable activity and showed increased strength both in inquiries and prices. The *benzene* market still remains in the same unsettled condition, with spot supplies practically exhausted even among second-hand dealers. Coke-oven operations have improved somewhat, but no effect will in any way be noticeable on the spot market for at least another month. *Naphthalene flakes* are firm, with the demand better from various quarters and quotations running around 7c. per lb. in second-hand channels and up to 8½c. per lb. from producers. Leading factors expect a rise soon. *Phenol* has shown some considerable improvement and large holders of prime material are quoting revised prices. Sellers holding large export orders were somewhat surprised to learn that all the better grade product is being withheld from the spot market at the present levels. Sales of prime white goods were made at 9½c. per lb. Sales of *dimethylaniline* were made at 60c. per lb., with other factors quoting up to 65c. per lb. The demand has shown that consumers have used the major portion of their old stocks and are eager to feel out the present market. Inquiries for *benzaldehyde* are being received in fairly good volume and sales for U.S.P. material were recorded at \$1.35 per lb. Resellers of *aniline oil* are maintaining prices around 18c. per lb., which is about the figure asked by producers. Buyers have not shown any real snap to trading and spot stocks have not been diminishing rapidly enough to keep prices steady.

WAXES

Importers of *beeswax* report a steady demand for the low grades and prices ruled quite steady. The crude African closed at 14@15c. per lb., with the Brazilian at 21@23c. per lb. Pure white refined was held at 34@38c. per lb. according to quantity and seller. Traders in *candelilla wax* reported a better demand, and prices were quoted higher at 25@25½c. per lb. Available stocks were somewhat limited. Spot offerings of *Japan wax* were reported at 22@24c. per lb. The general tone of this market was hardly steady, probably because of weak shipment prices. *Japan wax* for shipment closed at 16@16½c. per lb. c.i.f. New York. There were numerous offerings of *carnauba wax* in the market, but shipment prices showed very little change, leaving the general tone of the market practically unchanged. The demand was for small lots. No. 1 closed at 45c. per lb., with No. 2 North Country at 23c. per lb. The No. 3 North Country was held at 14½@15c. per lb. for prompt delivery. Prices on crude oil advanced sharply during the week, but this did not seem to have any noticeable effect on buyers of *paraffine wax*. Sellers have tried to advance prices in proportion to the advance in crude oil, but the movement did not show any signs of aggressiveness. Some large holders, on the other hand, have withdrawn from the market.

The St. Louis Market

ST. LOUIS, Mo., Nov. 11, 1921.

Activities in the chemical and drug markets continue to show increased signs of improvement and conditions as a whole have a very bright appearance. Dealings in the month of October increased considerably over those of preceding months and the first ten days of the present month show an appreciable increase over the same period of last month. It was expected that the calling off of the railroad strike would have a bad effect on the market for the more important commodities; however, this was not the case, as the demand continued, in fact, with a marginal increase.

Heavy importations of foreign chemicals have been noted for some time but with no ill effect on the domestic market, which leads us to suppose that the bulk of the importations is going direct to the consuming trade and not being distributed among second hands.

The general market shows no weakness and the tendency of manufacturers is to advance rather than follow the other direction, for many of the prices that are ruling are not consistent with manufacturing costs and have been forced only by the keen competition. Many of the more important items have taken an upward trend already, as for instance, *salicylates*, which took a sudden rise this week.

Buyers are more optimistic, as is evidenced by the increase in the volume of orders, further indicating that business is on the road to improvement.

ALKALIS

The market on *caustic soda* is very firm and continues at \$4 per 100 lb. for 73 to 75 per cent solid, f.o.b. point of production. No change in *soda ash*, *bicarbonate soda* or *sal soda*.

CHEMICALS, DRUGS AND PHARMACEUTICALS

Ammonia water, 26 deg., moves in routine way. An extraordinarily heavy demand for *sulphate ammonia*, pure granular, has been experienced the past several weeks and continues today. *Bismuth salts*, especially the *subnitrate*, is moving very strong in spite of the fact that this is the off season. *Bromides* are commanding a fair position. The heavy demand recently reported on *carbon bisulphide* has slowed up to some extent. *Cream of tartar* is experiencing a fair demand. *Creosotes* and *guaiacols* are now commanding a very good demand and this should continue for the reason that this is the season for these two commodities and large stocks should be carried. *Ethers* are moving freely. The photographic trade is making quite a demand for hydroquinone and recently manufacturers have reduced their schedule. *Hypo* is moving through regular channels at regular rates. Among the iodides, *iodine resublimed* and *potash* are the heavy sellers, at the present time, but the remainder of the *iodide salts* are also holding their own. Consumers are making a heavy demand on manufacturers for *salicylates*, especially the *acetyl salicylic acid*, of which there is an apparent shortage. The *salicylates* have also advanced the early part of this week. *Soda benzoate* continues to be in demand. Inquiries and demand for *thymol iodide* are very good. The demand for *zinc stearate* continues, although not much is expected of this commodity at this time, as the season is over. *Zinc sulphate*, pure granular, is moving in a lively way.

ACIDS

Manufacturers of heavy mineral acids report a continued increase in activities and look for further improvement in the near future. *Acid benzoic* is moving in a fair way. Fair quantities of *citric acid* are being sold, undoubtedly due to wholesalers' stocks being exhausted. *Gallie acid* and *pyrogallie acid* are in good demand; the manufacturers are in good position to fill large orders. *Acid tartaric* is moving in a routine way.

VEGETABLE OILS AND NAVAL STORES

Turpentine has stiffened very strongly during the last week, reaching price of 85c. in single barrels and 81c. in 5-bbl. lots ex-warehouse. *Castor oil* remains firm with prevailing price of 12½c. per lb. *Linseed oil* has advanced slightly over last week and is now moving at 70c. basis raw oil ex-warehouse.

The Iron and Steel Market

PITTSBURGH, Nov. 11, 1921.

Production of steel ingots in October was at the rate of about 44 per cent of capacity, the highest rate shown since February and more than double the rate of last July. There was a sharp increase July to August, a small increase August to September and a large increase September to October.

The Steel Corporation's unfilled obligations decreased by 273,841 tons during September, against an increase of 28,744 tons in September and decreases averaging about 500,000 tons a month in the 13 months preceding. The Steel Corporation's unfilled tonnage, long regarded as a useful index to business conditions, would be quite misleading if interpreted in the usual way, when increases have been regarded as favorable and decreases as unfavorable. The corporation entered this year with a large volume of contract business with customers. There was little occasion to enter additional tonnage, as customers were covered. Requirements of customers were indicated by their specifying against contracts. Shipments represented activity and decreased the unfilled tonnage. In March the corporation shipped its products at about 51 per cent of capacity and the unfilled tonnage decreased 649,102 tons. In July the corporation shipped at about 25 per cent and the unfilled tonnage decreased by only 287,544 tons. Which was the better month?

In each month, March to August inclusive, the new bookings of contract or other tonnage were very small, the decrease in unfilled obligations being but a trifle less than the shipments. In September two price advances occurred, in wire products and sheets respectively, bringing in considerable quantities of business at the old prices. The shipments were at about 34 per cent of capacity and the increase in unfilled obligations about 2 per cent, indicating that bookings were at about 36 per cent of capacity, easily the largest bookings for months. In October the shipments were at about 44 per cent of capacity, while the decrease in unfilled tonnage was about 20 per cent of capacity, indicating bookings at about 24 per cent.

STEEL PRICES

Finished steel prices in general exhibit a slight sagging tendency from week to week. In most if not all products there can be no clear cut declines for the simple reason that there are no clear cut prices. Sales occur at various prices according to the tonnage of order and the character of specifications, as well as the particular needs of a mill for rolling schedules at one time and another. There is, of course, quite free competition. Sales of bars, shapes and plates generally fall within the range of 1.50@1.60c. In sheets there are "regular" prices of 3c. on black and 4c. on galvanized, and these prices are shaded somewhat more than a week ago. In tubular goods there are published lists, the shading of which is more widespread than a week ago, though perhaps no deeper. Tin plate presents a stable market. For a long time several independents were shading the Steel Corporation price of \$5.25, the corporation departing from its common policy of 6 months or so past in the matter of recognizing price competition, but on Nov. 3 the corporation decided to reduce its price to \$4.75. At this price the market seems stabilized.

PROSPECTS

Recovery from the extremely low production rate of last July was unavoidable, because at that time consumption was being taken care of partly by stocks, and in time the stocks would be liquidated. The 44 per cent operating rate of last month involves a different condition, the production probably balancing the country's needs with general business of its present volume and character. So little steel is being taken by the railroads and so little is passing into large construction jobs that the remainder represents really a fairly large tonnage for the common everyday activities. The production of steel, measured in ingots, is just equal to production in 1906 and 1907, years of great activity and years in which much steel passed to railroads and into large construction undertakings. The general public, so to speak, is taking much more steel than in 1906 and 1907, although population has increased by only about 22 per cent.

Barium chloride.....ton	58 00	60 00	62 00	70 00
Barium dioxide (peroxide).....lb.	20	21	22	23
Barium nitrate.....lb.	07½	08	08½	09
Barium sulphate (precip.) (blanc fixe) lb.....lb.	04	04½	04½	05
Bleaching powder (see calc. hypochlorite).....lb.	—	—	—	—
Blue vitriol (see copper sulphate).....lb.	—	—	—	—
Borax (see sodium borate).....lb.	—	—	—	—
Brimstone (see sulphur, roll).....lb.	—	—	—	—
Bromine.....lb.	27	28	28½	30
Calcium acetate.....100 lbs.	1 85	2 00	—	—
Calcium carbide.....lb.	04½	04½	05	05½
Calcium chloride, fused, lump.....ton	23 50	24 00	24 50	25 50
Calcium chloride, granulated.....lb.	01½	02	02½	02½
Calcium hypochloride (bleach) powder 100 lb.....lb.	2 25	2 30	2 35	3 00
Calcium peroxide.....lb.	—	—	1 40	1 50
Calcium phosphate, tribasic.....lb.	—	—	15	16
Camphor.....lb.	—	—	85	90
Carbon bisulphide.....lb.	06½	06½	07	07½
Carbon tetrachloride, drums.....lb.	10½	10½	11	12
Carbonyl chloride, (phosgene).....lb.	—	—	60	75
Caustic potash (see potassium hydroxide).....lb.	—	—	—	—
Caustic soda (see sodium hydroxide).....lb.	—	—	—	—
Chlorine, gas, liquid-cylinders (100 lb.) lb.....lb.	08	09	09½	10
Chloroform.....lb.	—	—	40	43
Cobalt oxide.....lb.	—	—	2 00	2 10
Copperas (see iron sulphate).....lb.	—	—	—	—
Copper carbonate, green precipitate.....lb.	20	20½	21	22
Copper cyanide.....lb.	—	—	50	62
Copper sulphate, crystals.....lb.	05	05½	05½	06
Cream of tartar (see potassium bitartrate).....lb.	—	—	—	—
Epsom salt (see magnesium sulphate).....lb.	—	—	—	—
Ethyl Acetate Com. 85%.....gal.	—	—	80	90
Ethyl Acetate pure (acetic ether, 98% to 100%).....gal.	—	—	95	—
Formaldehyde, 40 per cent.....lb.	11	11½	11½	12½
Fusel oil, ref.....gal.	—	—	2 50	3 00
Fusel oil, crude.....gal.	—	—	1 50	1 75
Glauber's salt (see sodium sulphate).....lb.	—	—	—	—
Glycerine, C. P. drums extra.....lb.	—	—	14½	15
Iodine, resublimed.....lb.	—	—	3 50	3 60
Iron oxide, red.....lb.	—	—	12	18
Iron sulphate (copperas).....ton	18 00	19 00	20 00	23 00
Lead acetate.....lb.	—	—	10½	12½
Lead arsenate, powd.....lb.	15	15½	15½	16½
Lead nitrate.....lb.	—	—	15	20
Litharge.....lb.	07½	08	08½	09
Lithium carbonate.....lb.	—	—	1 40	1 50
Magnesium carbonate, technical.....lb.	08	08½	09	10
Magnesium sulphate, U. S. P.....100 lb.	2 50	2 75	—	—
Magnesium sulphate, technical.....100 lb.	—	—	1 10	1 75
Methanol, 95%.....gal.	—	—	66	68
Methanol, 97%.....gal.	—	—	70	72
Nickel Salt, double.....lb.	—	—	12	12½
Nickel salt, single.....lb.	—	—	14	14½
Phosgene (see carbonyl chloride).....lb.	—	—	—	—
Phosphorus, red.....lb.	40	41	42	45
Phosphorus, yellow.....lb.	—	—	30	35
Potassium bichromate.....lb.	11	11½	11½	12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar).... lb.	\$.15 — .16	\$0.27 — \$0.29
Potassium bromide, granular..... lb.	.15 — .16	.16 — .20
Potassium carbonate, U. S. P..... lb.	.04 — .04	.05 — .06
Potassium carbonate, 80-85%..... lb.	.08 — .08	.08 — .12
Potassium chlorate, crystals..... lb.	.05 — .06	.40 — .45
Potassium cyanide..... lb.	.05 — .06	.06 — .08
Potassium hydroxide (caustic potash).... lb.	.07 — .07	.08 — .09
Potassium iodide..... lb.	.18 — .19	.20 — .22
Potassium nitrate..... lb.	.28 — .29	.29 — .30
Potassium permanganate..... lb.	.21 — .21	.21 — .22
Potassium prussiate, red..... lb.		
Potassium prussiate, yellow..... lb.		
Rochelle salts (see sodium potas tartrate)		
Salammoniac (see ammonium chloride)....		
Salt soda (see sodium carbonate).....		
Salt cake (bulk)..... ton		20.00 — 22.00
Silver cyanide..... oz.		1.35 — 1.38
Silver nitrate..... oz.		.46 — .47
Soda ash, light..... 100 lb.	2.10 — 2.15	2.20 — 2.60
Soda ash, dense..... 100 lb.	2.35 — 2.40	2.45 — 2.70
Sodium acetate..... lb.	.04 — .04	.04 — .05
Sodium bicarbonate..... 100 lb.	2.00 — 2.25	2.50 — 2.75
Sodium bichromate..... lb.	.08 — .08	.08 — .08
Sodium bisulphate (nitre cake)..... ton	5.00 — 5.25	5.50 — 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.04 — .05	.05 — .06
Sodium borate (borax)..... lb.	.05 — .06	.06 — .07
Sodium carbonate (sal soda)..... 100 lb.	1.90 — 2.00	2.10 — 2.30
Sodium chloride..... lb.	.07 — .07	.08 — .08
Sodium cyanide..... lb.	.28 — .28	.29 — .30
Sodium fluoride..... lb.	.11 — .12	.12 — .14
Sodium hydroxide (caustic soda)..... 100 lb.	4.00 — 4.10	4.15 — 4.50
Sodium hyposulphite..... lb.	.07 — .07	.07 — .08
Sodium nitrite..... lb.	.25 — .26	.27 — .30
Sodium peroxide, powdered..... lb.	.04 — .04	.04 — .05
Sodium phosphate, dibasic..... lb.	.14 — .14	.15 — .15
Sodium potassium tartrate (Rochelle salts) lb.	.95 — 1.00	1.10 — 1.25
Sodium prussiate, yellow..... lb.	2.30 — 2.40	2.45 — 3.00
Sodium silicate, solution (40 deg.)..... 100 lb.	1.50 — 1.75	2.00 — 2.25
Sodium silicate, solution (60 deg.)..... 100 lb.	.04 — .05	.05 — .05
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	.03 — .03	.04 — .04
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.12 — .13	.13 — .20
Sodium sulphite, crystals..... lb.	.05 — .05	.05 — .06
Strontium nitrate, powdered..... lb.	18.00 — 20.00	.09 — .10
Sulphur chloride, red..... ton	.08 — .08	.25 — 3.10
Sulphur, crude..... lb.		2.00 — 2.75
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 — .09	.09 — .10
Sulphur (sublimed), flour..... 100 lb.	.16 — .16	.17 — .17
Sulphur, roll (brimstone)..... 100 lb.	.09 — .09	.09 — .10
Tin bichloride..... lb.	.42 — .44	.45 — .47
Tin oxide..... lb.	.11 — .11	.11 — .12
Zinc carbonate, precipitate..... lb.	.07 — .07	.08 — .09
Zinc chloride, gran..... lb.	3.00 — 3.25	3.30 — 3.50
Zinc cyanide..... lb.		
Zinc dust..... lb.		
Zinc oxide, XX..... lb.		
Zinc sulphate..... 100 lb.		

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 — \$1.20
Alpha-naphthol, refined..... lb.	1.25 — 1.30
Alpha-naphthylamine..... lb.	.27 — .30
Aniline oil, drums extra..... lb.	.18 — .20
Aniline salts..... lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.35 — 1.45
Benzidine, base..... lb.	.90 — 1.00
Benzidine sulphate..... lb.	.75 — .85
Benzoic acid, U.S.P..... lb.	.60 — .65
Benzoate of soda, U.S.P..... lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 — .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 — .28
Benzyl chloride, 95-97%, refined..... lb.	.25 — .27
Benzyl chloride, tech..... lb.	.20 — .23
Beta-naphthol benzoate..... lb.	3.75 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75
Beta-naphthol, tech..... lb.	.31 — .34
Beta-naphthylamine, sublimed..... lb.	1.75 — 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 — .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 — .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 — .50
Dichlorobenzene..... lb.	.06 — .09
Diethylaniline..... lb.	1.10 — 1.20
Dimethylaniline..... lb.	.45 — .60
Dinitrobenzene..... lb.	.23 — .27
Dinitrochlorobenzene..... lb.	.20 — .25
Dinitronaphthalene..... lb.	.30 — .35
Dinitrophenol..... lb.	.35 — .40
Dinitrotoluene..... lb.	.25 — .30
Dip oil, 25%, car lots, in drums..... gal.	.30 — .35
Diphenylamine..... lb.	.60 — .70
H-acid..... lb.	1.05 — 1.15
Meta-phenylenediamine..... lb.	1.15 — 1.20
Monochlorobenzene..... lb.	.12 — .14
Monothylaniline..... lb.	1.65 — 1.70
Naphthalene crushed, in bbls..... lb.	.07 — .08
Naphthalene, flake..... lb.	.07 — .08
Naphthalene, balls..... lb.	.08 — .09
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35
Nitro-toluene..... lb.	.15 — .17
Ortho-amidophenol..... lb.	3.00 — 3.10
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80
Ortho-nitro-toluene..... lb.	.15 — .20
Ortho-toluidine..... lb.	.20 — .25
Para-amidophenol, base..... lb.	1.40 — 1.45
Para-amidophenol, HCl..... lb.	1.70 — 1.80
Para-dichlorobenzene..... lb.	.12 — .15
Paranitroaniline..... lb.	.77 — .80
Para-nitrotoluene..... lb.	.80 — .85
Para-phenylenediamine..... lb.	1.70 — 1.75
Para-toluidine..... lb.	1.25 — 1.40
Phthalic anhydride..... lb.	.40 — .50

Phenol, U. S. P., drums..... lb.	.09 — .12
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	1.50 — 1.60
Resorcinol, pure..... lb.	2.00 — 2.25
Salicylic acid, tech., in bbls..... lb.	.18 — .20
Salicylic acid, U. S. P..... lb.	.19 — .22
Salol..... lb.	.70 — .72
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 — .16
Sulphanilic acid, crude..... lb.	.27 — .30
Tolidine..... lb.	1.30 — 1.35
Toluidine, mixed..... lb.	.43 — .45
Toluene, in tank cars..... gal.	.25 — .28
Toluene, in drums..... gal.	.28 — .31
Xylidines, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.40 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.21 — \$0.22
Beeswax, refined, dark..... lb.	.24 — .25
Beeswax, refined, light..... lb.	.28 — .30
Beeswax, white pure..... lb.	.34 — .38
Candellila wax..... lb.	.25 — .25
Carnauba, No. 1..... lb.	.45 — .46
Carnauba, No. 2, North Country..... lb.	.23 — .23
Carnauba, No. 3, North Country..... lb.	.14 — .15
Japan..... lb.	.22 — .22
Montan, crude..... lb.	.04 — .04
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 — .04
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 125 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 — .05
Paraffine waxes, refined, 133-135 m.p..... lb.	.05 — .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 — .06
Stearic acid, single pressed..... lb.	.09 — .09
Stearic acid, double pressed..... lb.	.10 — .10
Stearic acid, triple pressed..... lb.	.11 — .11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.80 — 5.80
Rosin E-I..... 280 lb.	5.85 — 5.90
Rosin K-N..... 280 lb.	6.40 — 6.85
Rosin W. G. W. W..... 280 lb.	7.10 — 7.30
Wood rosin, bbl..... 280 lb.	6.25 — .
Spirits of turpentine..... gal.	.80 — .
Wood turpentine, steam dist..... gal.	.78 — .
Wood turpentine, dest. dist..... gal.	.76 — .
Pine tar pitch, bbl..... 200 lb.	. — 6.50
Tar, kiln burned, bbl. (500 lb.)..... bbl.	. — 10.00
Retort tar, bbl..... 500 lb.	. — 10.00
Rosin oil, first run..... gal.	.35 — .
Rosin oil, second run..... gal.	.37 — .
Rosin oil, third run..... gal.	.44 — .
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.90 — .
Pine oil, pure, dest. dist..... gal.	1.50 — .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 — .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 — .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 — .
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 — .
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 — .
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 — .
Pinewood creosote, ref..... gal.	.52 — .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 — .
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 — .
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 — .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 — .

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.50 — 3.00
Blood, dried, f.o.b., N. Y..... unit	4.00 — .
Bone, 3 and 50, ground, raw..... ton	30.00 — 32.00
Cyanamide, f.o.b. works..... unit	4.50 — .
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 — 3.00
Nitrate soda..... 100 lb.	2.35 — 2.45
Tankage, high grade, f.o.b. Chicago..... unit	3.00 — 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 — 6.50
Tennessee, 78-80 p.c..... ton	8.50 — 9.00
Potassium muriate, 80 p.c..... ton	37.00 — 40.00
Potassium sulphate..... unit	1.00 — 1.10

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 — .21
Upriver coarse..... lb.	.11 — .12
Upriver cauchoo ball..... lb.	.11 — .12
Plantation—First latex crepe..... lb.	.15 — .15
Ribbed smoked sheets..... lb.	.15 — .15
Brown crepe, thin, clean..... lb.	.15 — .
Amber crepe No. 1..... lb.	.17 — .

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 — \$0.10
Castor oil, A.A. in bbls..... lb.	.11 — .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 — .13
Cocanut oil, Ceylon grade, in bbls..... lb.	.09 — .09
Cocanut oil, Cochui grade, in bbls..... lb.	.10 — .10
Corn oil, crude, in bbls..... lb.	.10 — .10
Cottonseed oil, crude (f. o. b. mill)..... lb.	.06 — .07
Cottonseed oil, summer yellow..... lb.	.08 — .09
Cottonseed oil, winter yellow..... lb.	.09 — .09

Linseed oil, raw, ear lots (domestic)	gal.	67	—	68
Linseed oil, raw, tank cars (domestic)	gal.	62	—	63
Linseed oil, in 5-bbl lots (domestic)	gal.	70	—	71
Olive oil, Denatured	gal.	\$1.15	—	\$1.20
Palm, Lagos	lb.	.07½	—	.07¾
Palm, Niger	lb.	.06½	—	.06¾
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08½	—	.08¾
Peanut oil, refined, in bbls.	lb.	.11½	—	.11¾
Rapeseed oil, refined in bbls.	gal.	.84	—	.86
Rapeseed oil, blown, in bbls.	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.09	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.	lb.	.07½	—	

FISH

Light pressed menhaden	gal.	\$0.40	—	
Yellow bleached menhaden	gal.	.42	—	
White bleached menhaden	gal.	.45	—	
Blown menhaden	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri	net ton	7.00	—	
Blanc fixe, dry	lb.	.04	—	.04½
Blanc fixe, pulp	net ton	45.00	—	55.00
Casein	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light	lb.	.04½	—	.05
Chalk, Precipitated, domestic, light	lb.	.04	—	.04½
Chalk, Precipitated, domestic, heavy	lb.	.03½	—	.04
Chalk, Precipitated, English, extra light	lb.	.04½	—	.05
Chalk, Precipitated, English, light	lb.	.04½	—	.05
Chalk, Precipitated, English, dense	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	13.00	—	20.00
China clay (kaolin), imported, lump	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.	net ton	18.00	—	
Fullers earth, imported, powdered	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality	lb.	.06	—	.07
Graphite, Ceylon chip	lb.	.04½	—	.05
Graphite, high grade amorphous crude	lb.	.00¾	—	.02½
Kieselguhr, f.o.b. mines, Cal.	per ton	40.00	—	
Kieselguhr, f.o.b. N.Y.	per ton	55.00	—	60.00
Magnesite, calcined	per ton	60.00	—	65.00
Pumice stone, imported	lb.	.03	—	.40
Pumice stone, domestic, lump	lb.	.05	—	.05½
Pumice stone, domestic, ground	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina	net ton	5.00	—	7.50
Shellac, orange fine	lb.	.68	—	.70
Shellac, orange superfine	lb.	.78	—	.80
Shellac, A. C. garnet	lb.	.58	—	.60
Shellac, T. N.	lb.	.68	—	.70
Soapstone	ton	12.00	—	15.00
Sodium chlorate	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont	ton	11.00	—	18.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TUSCALOOSA—F. G. Blair, Tuscaloosa, will head the new company now being organized under the auspices of the local Chamber of Commerce, J. B. Brosius, secretary, to construct and operate a new plant for the manufacture of bond and kraft paper. The company will be capitalized at \$2,000,000, and the new mills are estimated to cost close to \$1,000,000. It is proposed to develop a daily production of about 50 tons.

California

MERCED—The California Pottery Co. has begun operations at its new local plant, placing 4 kilns, recently completed, in service. The initial unit will comprise a total of 16 kilns, and these will be completed and placed in operation as quickly as possible. Employment will be given to about 30 operatives, and this number will be gradually increased as the plant expands.

LOS ANGELES—The International Shales Process Co. has awarded a contract to the Golden State Construction Co., 415-17 Delta Bldg., for the erection of a series of distillation plants for oil-refining operations in California, Utah, Nevada and Colorado. Each plant unit is estimated to cost close to \$90,000, and it is said that a total of 100 plants will be constructed. The first refinery will be located in Kern County.

Connecticut

NEW HAVEN—The New York, New Haven & Hartford R.R. Co. has awarded a contract to the American Creosoting Co., 17 Battery Pl., New York, for the erection of a new local creosoting treatment plant for railroad ties, with annual capacity of about 1,500,000 cross-ties. It is expected to have the plant ready for operation during the coming spring.

Delaware

SOUTH WILMINGTON—The Wilmington Sugar Refining Co. is pushing construction on its new local refinery, and expects to have the entire project completed within 24 months; certain units will be ready prior to this time and placed in operation. The plant will occupy a 12-acre site in the vicinity of B St., and will consist of a total of 10 buildings, estimated to cost, with machinery, in excess of \$7,000,000. A wharf about 800 ft. long will be built along the Christiana River. The Armstrong & Latta Co., Land Title Bldg., Philadelphia, Pa., has the erection contract.

Illinois

CICERO—The Oriental Glass Manufacturing Co. has purchased 10 acres at West 33d St. and 52nd Ave., Cicero, for the erection of a glass factory to cost \$175,000 and will manufacture colored sheet glass. The plant will be complete for operation within the next three months.

CHICAGO—Paul G. Carhardt, architect, is preparing plans for a 2-story concrete and mill construction dyeing plant, 500 x 150 ft., to be built at Grand Ave. near 54th Ave.

Maryland

POCOMOKE CITY—The Pocomoke City Roller Mills has preliminary plans under way for the erection of a new flour mill on local site. It will be 3-story and basement, 40 x 55 ft., and is estimated to cost about \$35,000. Bids for construction are expected to be called near the close of the year. W. S. Jewell heads the company.

BALTIMORE—Fire, Oct. 29, destroyed one of the plants of the Baltimore Brick Co., Maryland Trust Bldg., at Highland Ave. and Monument St., with loss estimated at close to \$100,000. The loss included 5 kiln buildings, machine shops, power house and other structures. It is said that the plant will be rebuilt. Warren Griffiss is general manager.

BALTIMORE—The Cooknut Corp., Lexington and Paea Sts., has construction

under way on its new 4-story plant, 80 x 100 ft., on Canton St., to be equipped for the manufacture of lard substitutes, estimated to cost about \$100,000 with machinery. W. R. Spruill is president.

CRISFIELD—The Standard Oil Co., Pratt St., Baltimore, is considering the construction of a large oil-distributing plant at Crisfield, and a number of available sites are being inspected. It is purposed to make this the main distributing works in the central Atlantic coast district, and extensive tankage and equipment will be provided.

Massachusetts

PITTSFIELD—The Pittsfield Lime & Stone Co. has plans under way for enlargements in its plant at Richmond Summit. Four new kilns will be constructed and present kilns altered and improved. New operating equipment will be installed.

ROXBURY—Fire, Oct. 31 destroyed a building at 10 Hampden St., occupied by the Chadwick-Boston Lead Co., for general service, with loss estimated at about \$30,000.

BOSTON—The Tileston & Hollingsworth Co., 892 River St., Hyde Park, manufacturer of paper products, has construction under way on a new plant addition on River St., to be equipped as a paper washery. It is estimated to cost about \$23,000. The Aberthaw Construction Co., 27 School St., Boston, has the erection contract.

WORCESTER—The American Steel & Wire Co. is building a 3-story addition to its South Works, 120 x 145 ft., estimated to cost about \$150,000. It is expected to have the structure ready for service at an early date.

Minnesota

MINNEAPOLIS—The Minnesota Mfg. Co., 722 North Third St., manufacturer of sweeping compounds and other chemical specialties, is taking new bids for the erection of a 3-story plant on Eighth Ave., near Third St., estimated to cost about \$35,000. It will be 46 x 130 ft. E. J. Miller is secretary.

Missouri

SPRINGFIELD—The Bromite White Lime Co., Woodruff Bldg., is considering the erection of a new 2-story and basement plant, with cost estimated at about \$50,000. It is expected to have plans drawn at an early date. D. F. Klepinger is secretary.

COLUMBIA—The Edwards Brick Co., St. Louis, recently reorganized with a capital of \$50,000, is planning for the establishment of a new plant at Columbia for the manufacture of brick and other burned clay products. S. E. Cullom is ceramic engineer for the company.

Nebraska

OMAHA—The Omaha Semi-Steel Foundry Co., 1409 Jackson St., has taken bids for the erection of a new 1- and 2-story foundry at Eleventh and Grace Sts., 60 x 100 ft., and will commence construction at an early date. W. F. Gernandt, 701 O. L. & B. Association Bldg., is architect.

New Jersey

NEWARK—Fire, Oct. 29, destroyed a portion of the plant of the Thrift Rubber Co., Woosyc St., Irvington, with loss estimated at about \$10,000.

WHARTON—The Replogle Steel Corp. is completing extensions and improvements at its local plant, under way for some time past, and will hold the works in readiness to operate as soon as market conditions warrant. The steel plant consists of two blast furnaces and a sintering plant, with auxiliary departments, said to be valued in excess of \$5,000,000.

EDGEWATER—The Archer Daniels Linseed Co., 20 Ninth Ave., Minneapolis, Minn., has awarded a contract to the Tilt-Hargan Co., 90 West Broadway, New York, for the erection of its new plant at Edgewater. It will consist of a main 3-story oil works, 150 x 250 ft.; three 1-story warehouse buildings; four grain tanks, each about 100 ft. high; and electric power plant for operation. Work will be commenced at once. Samuel Mairs is secretary.

North Carolina

MONROE—The Hender on Rolling Mills Co. has awarded a contract to J. S. Sterns, Monroe, for the erection of a new flour mill on local site, estimated to cost about \$40,000. J. E. Henderson is president.

CHARLOTTE—The North Charlotte Creosoting Co., recently organized with a capital of \$100,000, is planning for the erection of a new creosoting plant for timber treatment, with initial capacity of about 50,000 ft. of material per day. A retort, 68 ft. long, will be constructed in connection with the other works departments.

Ohio

ASHTABULA—The Silurim Mfg. Co., 421 Sloan Bldg., Eugene W. Steinbrenner, president, has plans under way for the erection of a new plant at Ashtabula, for the manufacture of rubber insulating materials. It will be 4-story, brick, and is estimated to cost in excess of \$750,000, including machinery. Alfred W. Harris, Schofield Bldg., Cleveland, is architect.

YOUNGSTOWN—The Vahey Oil Co. has plans under way for the erection of a new 1-story building on West Rayen St. Stanley & Scheibel, Wick Bldg., are architects. W. H. Vahey is president.

AKRON—A. C. Horrocks, formerly connected with the local plant of the Goodyear Tire & Rubber Co., has organized a new company with capital of \$50,000, for the manufacture of rubber specialties. The new organization has leased the plant of the Denmead Rubber Co., and will commence operations at an early date.

Pennsylvania

PHILADELPHIA—Horace T. Potts & Co., 316 North Third St., manufacturer of iron and steel products, has broken ground for the erection of a new 1-story foundry at Erie Ave. and D Sts., to be used in connection with an extensive new plant at this location. The William Steele & Sons Co., 1600 Arch St., is contractor.

SCRANTON—The Diamond Oil & Paint Co., 211-19 South Seventh Ave., has taken bids and will soon award contract for the erection of a new 2-story building, 60 x 100 ft., on Seventh Ave., estimated to cost about \$60,000. Edward J. Lynott is president.

PHILADELPHIA—The Wittman Moriarty Co., Fourth and Vine Sts., manufacturer of leather products, has taken bids for the erection of an addition to its tanning plant at Ontario and C Sts. Work will be commenced at an early date.

South Carolina

SPARTANBURG—Caldwell & Co., manufacturers of cottonseed products, are planning for the erection of a new plant, about 25 x 65 ft. Ralph M. Caldwell is secretary and manager.

Tennessee

KNOXVILLE—The Knoxville Fertilizer Co. has awarded a contract to the Foundation Co., 120 Liberty St., New York, for the erection of its proposed new plant in Vestal section, to be 154 x 350 ft., and estimated to cost about \$200,000. The plant will be equipped for an annual output of about 50,000 tons of acid phosphate. Manley & Young 814 West Hill Ave., are engineers. James W. Dean is secretary-treasurer.

Texas

MEXIA—The Texas-Mexia Co. will soon commence the installation of a 50-bbl. still at its properties, and plans for the installing of other equipment at its refinery for increased output.

DALLAS—The Superior Chemical Products Co., recently organized, has acquired the plant of the Southern States Chemical Co., and will use the works for the manufacture of general chemicals for fire-extinguishing and other service.

WACO—The Southwestern Portland Cement Co., El Paso, has preliminary plans under way for its proposed new mill in the vicinity of Waco, estimated to cost in excess of \$2,000,000. O. J. Binford is secretary.

Virginia

LYNCHBURG—The Kerr & Wilson Co. has completed plans and will soon commence the erection of a new plant at South Roanoke, Va., for the manufacture of wood extract products. It will be 1-story, 80 x 130 ft.; estimated cost about \$30,000.

West Virginia

MORGANTOWN—The University of West Virginia has preliminary plans under way for the erection of a new chemical laboratory, estimated to cost about \$400,000. Bids will be asked early in 1922. Lee Coulter is dean.

Industrial Notes

BEN L. WHITNEY, formerly with the Byers Company, has opened an office at 528 Detroit Savings Bank Bldg., Detroit, Mich., as representative of Orton & Steinbrenner Co., manufacturer of material handling machinery, coal crushers, drag-line excavators, locomotives, etc.

THE YORK HEATING & VENTILATING CORP., Philadelphia, Pa., announces that Thornton Lewis, who for the last fifteen years has been associated with the Buffalo Forge Co. and actively identified with the heating, ventilating and air-conditioning profession, has joined the organization as vice-president and general manager. He is a member of the executive committee in charge of the research laboratory established by the American Society of Heating and Ventilating Engineers at the Bureau of Mines, Pittsburgh. During the war period Mr. Lewis was consulting engineer for the du Pont companies of Wilmington, Del., having charge of the design and supervision of all heating, ventilating and drying installations. This company recently moved from York, Pa., to Bridgeport, Pa., where it has a plant of 50,000 sq. ft. of floor space with a 400-ft. frontage on the Reading railroad.

THE QUIGLEY FURNACE SPECIALTIES CO., INC., New York, announces that its pulverized fuel department has been acquired by the Hardinge Co., New York. The Hardinge Co. states there will be no change in the method of conducting the business at its offices, as the organization of the engineering department has been taken over practically intact. This transfer will in no way affect the refractory specialties business, which includes the manufacture and sales of Hytempite, Insulbrix and Insuline products.

CHICAGO PNEUMATIC TOOL CO. advises the public that it has brought suit in the United States District Court in the Western District of Michigan against the Keller Pneumatic Tool Co. for injunction and accounting of profits and damages due to alleged infringements of certain United States patents by their manufacture and sale of the so-called "Keller-Master Super-Hammer." The patents involved are Nos. 879,106, 897,958, 1,029,082 and 1,126,096. Suit has also been brought against the H. Channon Co. in the United States District Court at Chicago for alleged infringement by the sale and offering for sale of the above-mentioned Keller hammers and for unfair competition by acts calculated to produce confusion in the trade. These suits should not be confused with the one heretofore brought against the Keller Pneumatic Tool Co. in the United States District Court at Philadelphia for alleged infringement of patents 730,887, 822,147, 866,573 and 917,242, which suit is being vigorously prosecuted. Suit is also pending in the United States District Court at Chicago against the Keller Pneumatic Tool Co. for alleged infringement by the use of the trade name "Keller" and certain other trademarks of the Chicago Pneumatic Tool Co.

Capital Increases, Etc.

THE METROPOLITAN OIL CORP., Indianapolis, Ind., a Delaware corporation, has filed notice of increase in capital from \$5,000,000 to \$10,000,000.

THE LOUIS J. ROBINSON TANNING CO., a New Jersey corporation, has filed notice of organization to operate in New York, with capital of \$100,000. The company is represented by L. J. Robertson, 450 West End Ave.

THE MANITO CHEMICAL FERTILIZER CO., 1205 Lehmann Bldg., Peoria, Ill., has filed notice of change of name to the Manito Chemical Co., at the same time increasing its capital from 2,000 shares of stock, no par value, to \$150,000.

THE OJOY CHEMICAL CO., INC., Syracuse, N. Y., has filed a voluntary petition in bankruptcy, with liabilities stated at \$20,317 and assets, \$6,975.

THE MICHIOAN PAINT CO., Detroit, Mich., has filed notice of dissolution under state laws.

THE ACORN BRASS MFG. CO., 426 South Clinton St., Chicago, Ill., has filed notice of reduction in capital from \$30,000 to \$15,000.

THE TAYLOR-WARTON IRON & STEEL CO., 30 Church St., New York, N. Y., manufacturer of alloy steel and iron castings, etc., with plant at High Bridge, N. J., has arranged for a bond issue to total \$3,250,000.

Daniel J. O'Connell has been appointed receiver for the HAMILTON PAPER BOX CO., 69 Greene St., New York, N. Y.

New Companies

THE PHILADELPHIA ASBESTOS CO., Philadelphia, Pa., has been incorporated with a capital of \$12,000, to manufacture asbestos products. J. W. Hoffman, Jr., 5226 North Fairhill St., is treasurer.

THE MIOLA CHEMICAL CORP., Montclair, N. J., has been incorporated with a capital of \$25,000, to manufacture chemical products. The incorporators are Paul H. Sullivan, Charles S. Shirley and James E. Lally, 88 Grove St., Montclair.

THE AMERICAN-MEXICAN REFINING CO., 11 South La Salle St., Chicago, Ill., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are N. O. Johnson, D. A. Tasiopoulos, and Henry L. Blim.

THE CLAY CRAFT POTTERIES, INC., Los Angeles, Cal., has been incorporated with a capital of \$300,000, to manufacture pottery specialties. The incorporators are E. R. Carpenter, Los Angeles; W. P. Yoo and M. H. Carpenter, Glendale, Cal.

THE NEPON DRUG & CHEMICAL CO., Rockaway Park, L. I., has been incorporated with a capital of \$50,000, to manufacture chemicals, chemical byproducts, drug specialties, etc. The incorporators are T. J. Smith, G. F. Wolfe and J. Clark. The company is represented by Joseph Shalleck, 152 West 42d St., New York.

THE REED & FIBRE CORP., Gardner, Mass., has been incorporated with a capital of \$50,000, to manufacture fiber products and affiliated specialties. Maurice J. Taub is vice-president; and Nathan Gewandter, 62 A St., Gardner, treasurer.

THE EAGLE CEMENT CORP., Jersey City, N. J., has been incorporated with a capital of \$150,000, to manufacture cement products. The company is represented by the United States Corporation Co., 15 Exchange Pl., Jersey City.

THE UNION BLUE CORP., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture blueing, chemical specialties, etc. The incorporators are S. and L. Pressner, and B. Frankel. The company is represented by G. C. Young, 165 Broadway, New York.

THE ROMANITE PRODUCTS CORP., Buffalo, N. Y., has been incorporated with a capital of \$500,000, to manufacture tile specialties, composition products, etc. The incorporators are E. A. Willson, A. L. Kink and R. M. Houser, 702 Mutual Life Bldg., Buffalo.

THE CHICAGO CHINA DECORATING WORKS, INC., 1529 West 21st St., Chicago, Ill., has been incorporated with a capital of \$20,000, to manufacture chinaware and other pottery products. The incorporators are Jacob Williamson, Edwin M. Conway and R. E. Leopold.

THE SOUTHERN PINE PRODUCTS CO., Biloxi, Miss., has been incorporated under Delaware laws with capital of \$2,000,000, to manufacture turpentine, rosin and kindred products. The incorporators are D. J. and E. C. Gay, Biloxi; and J. O. Gillespie, Gulfport, Miss. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE LANSDALE PORCELAIN ENAMEL WORKS, INC., Lansdale, Pa., has been incorporated with a capital of \$30,000, to manufacture porcelain products and other ceramic specialties. Abraham H. Landis, Lansdale, is treasurer.

THE PROGRESS PROCESS CO., Louisville, Ky., has been incorporated under Delaware laws with capital of \$660,000, to manufacture chemicals, chemical byproducts, etc. The incorporators are T. K. J. Blakely and James P. Helm, Louisville. The company is represented by the Corporation Trust Co. of America, duPont Bldg., Wilmington, Del.

THE SALINA CHEMICAL CO., Syracuse, N. Y., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are C. J. Dence, C. E. Brownell and M. B. Eldredge. The company is represented by C. R. Milford, Skaneateles, N. Y.

THE JEWEL MFG. CO., Lansing, Mich., has been incorporated with a capital of \$30,000, to manufacture soaps, chemical products, etc. The incorporators are Louis Simon and Herman C. Nielsen, Lansing, Mich.

THE FEDERAL PAINT & VARNISH CO., Boston, Mass., has been incorporated with a capital of \$25,000, to manufacture paints, varnish, etc. Benjamin J. Bond is president; and E. C. Meyer, 24 Seaver St., Roxbury, Mass., treasurer.

KIRBACH, INC., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are H. Kir-

bach, E. G. Hothorn and F. R. Fox. The company is represented by C. S. Aronstam, 100 Broadway, New York.

INDUSTRIAL LABORATORIES, INC., 1 Montgomery St., Jersey City, N. J., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are Frank E. Williamson, Carl W. von Helmsolt and William G. Clarke.

THE EDIBLE OILS REFINING CORP., 140 South Dearborn St., Chicago, Ill., has been incorporated with a capital of \$20,000, to manufacture refined oil products. The incorporators are Taylor E. Brown, Clifford J. Thompson and David E. Peterson.

THE PEERLESS TANNING CO., Salem, Mass., has been incorporated with a capital of \$10,000, to manufacture leather products. Theodore T. Granes is president; and Wallace F. Haley, 35 Pleasant St., Salem, treasurer.

THE PURITAN PETROLEUM CO., New York, N. Y., has been incorporated under Delaware laws with capital of \$5,000,000, to manufacture oil products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE NILE QUEEN CORP., 3425 Indiana Ave., Chicago, Ill., has been incorporated with a capital of \$200,000, to manufacture chemicals and chemical byproducts. The incorporators are J. Delos Bell, George H. Walker and Claude A. Barnett.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Emerson Hotel.

AMERICAN IRON AND STEEL INSTITUTE will hold its twentieth general meeting at the Hotel Commodore, New York City, on Friday, Nov. 18.

AMERICAN PETROLEUM INSTITUTE will hold its second annual meeting at the Congress Hotel, Chicago, Dec. 6, 7 and 8.

COLLEGE OF THE CITY OF NEW YORK, department of chemistry, will give public lectures under the auspices of the City College Chemical Society in the Doremus Lecture Theater, at 4:30 p.m., as follows: Nov. 17, "The Significance of the Coal Tar Dye Industry," by Dr. Ellwood Hendrick, consulting Editor, CHEM. & MET.; Nov. 30, "Afterthoughts of the War," by Leland L. Summers, of the War Industries Board; Dec. 6, "America in Chemistry," by Dr. Edgar F. Smith, provost emeritus, University of Pennsylvania, and president, American Chemical Society.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting. Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Pointing the Way To Industrial Peace

FRIENDLY criticism is always welcome, especially when it comes from one who has succeeded in solving some of the same sort of problems that have been puzzling us. And this is one of the accomplishments of B. SEEBOHM ROWNTREE, a highly successful manufacturer of York, England, who has spent two months in the United States studying methods and conditions in our industries. His public addresses have been of particular interest to American business men because they offer a keen analysis of our industrial relations by one who is recognized as an authority on the social aspects of industry.

Mr. ROWNTREE tells us that although the American manufacturer leads the world in the application of science to the material problems of his business, his relations with his employees are still guided by the crudest of rule-of-thumb methods. He is willing to spend his money for costly excursions into abstract science, but he is often inclined to regard the recommendations of his industrial manager as too idealistic to be of practical application. The American executive attempts to increase the efficiency of his plant by improving industrial processes and by eliminating wastes in production, but he does not give commensurate consideration to the problems of labor and its growing spirit of unrest. The British manufacturer, although perhaps not quite as alert nor as aggressive, has far outstripped his American brother in the progress toward industrial peace. He has put into actual operation many of the schemes which appear Utopian to most of us.

Our visitor's principal criticism of the employer, as a class, is that he is unimaginative. He sees business through his own eyes, to which labor is but a commodity which disturbs his plans and threatens his profits. As long as this attitude remains unchanged, industrial unrest will continue to be regarded as a necessary adjunct of industry. Mr. ROWNTREE maintains that such a misconception can and must be corrected, but that this will not be accomplished by conflict nor by any scheme which attempts to recast or revolutionize the entire industrial system. He gives us five minimum conditions which, in his opinion, constitute the price which must be paid for industrial peace: (1) Wages must be sufficient to permit the worker to live in reasonable comfort. (2) Working hours must be such as will give the worker adequate opportunities for recreation and self-expression. (3) There must be an increased economic security for the worker, notably with regard to the menace of unemployment. (4) The employee must share with the employer in determining working conditions. (5) The worker must receive a direct interest, if possible, in the profits of the industry in which he is engaged.

Many American manufacturers will no doubt offer practical objections to this platform, but the fact remains that in Great Britain most of these principles are being applied with conspicuous success. Unemployment measures, wage equalization funds, pensions, workers' councils and profit-sharing schemes have made greater headway in British industries than in our own. If it is true that our industries have had a lopsided development, that we have emphasized the material and neglected the human aspects of business, then American executives can profit by Mr. ROWNTREE'S friendly criticism and constructive suggestions.

Classification Of Research

IN THE department headed "Readers' Views and Comments" is published a letter from Dr. HYDE, commenting upon our editorials entitled "When Is a Research a Mere Inquiry?" (Oct. 5) and "How May Research Be Fostered?" (Oct. 12). Dr. HYDE calls attention to a classification of research activities published in the first of these editorials, and ascribed to him, but which is in error. The editors must plead guilty of the fault, and gladly give space to the diagram used by Dr. HYDE, a duplicate of which was unfortunately not in hand. Inspection of the two will show that both of us are in agreement that "Research" should not apply to all kinds of work mentioned—in fact Dr. HYDE classifies some of it as plain "Engineering" rather than "Engineering Research."

Obviously we made no effort to appraise research activities in a critical manner and from many angles. An opportunity was taken, however, to protest in as vigorous a manner as possible—and to this end we used certain literary license in overdrawing an opposite picture merely to emphasize the point—against an indiscriminate use of the word "Research." Fortunately, perhaps, for the English language, the dictum of even so powerful an organ as CHEMICAL & METALLURGICAL ENGINEERING is unable to change the accepted usage of words! And since dictionaries follow usage rather than lead in developing language, definitions of research can easily be found that would include those investigations that Dr. HYDE wishes to exclude. And doubtless a little search in our own columns would convict us of the same fault against which we are declaiming.

Nevertheless, we beg of you, be a little more careful in the use of words—precision in this is as desirable as in any other activity or observation. There are real differences between research, investigation, inquiry, scrutiny, experimentation, testing. With the wonderful resources of the English language available, it is a shame to debase it into jargon. Not all experimenters are researchers; not all surveyors are engineers.

Apropos of Getting a Job

HE WAS a graduate chemical engineer from a good institution, and looking for work. He asked the old man if he couldn't recommend him somewhere. The old man asked him in return to name any of his qualifications that he could indicate as warranting his employment. The younger one thought the name of his *alma mater* a sufficient guaranty of his merit. Then the old chemist proceeded:

"The open door of opportunity is narrow and there are many trying to crowd through it. You stand now on the outside of the crowd, all trying to get in. On the other side of it a few good men are wanted, but are you any better than the rest of the crowd?"

"No, I don't profess to be a genius. All I claim is to be a good graduate chemical engineer without experience."

"I'm afraid you are not even a good graduate. Here is American industry sorely in need of applied chemistry, and hardly anyone to apply it until somebody shows the world just how it is done. That's the trouble with you fellows outside the door: you're unwilling to think. You want to get in, and then have somebody nurse you along until you are taught enough things that others know, to have earning capacity. It is a proper attitude for an apprentice, but it is not the proper attitude for a professional man.

"Let's take a look about us. There is the sulphuric acid works, the rubber works, the coke plant, and the tar refinery. You say they don't want any more chemists, and you observe the crowd trying to get in. If you were to succeed, I doubt if you would be of much use to any of them. You will have to be born again, if you want to be a good chemical engineer, and what I am trying to do now is to start you in the process of being born again.

"Do you see the big bakery over there? See the candy factory? See the two big laundries? See the new hotel with its immense restaurant?"

"But they don't want any chemists!"

"Yes, they do. They don't wish for them, but chemistry is just what they lack. Of course the men at the head of the concerns don't know it, but that is where your chance comes in. If they knew they needed chemists, they would call for specially trained men, and you wouldn't have any show at all. When your friend STEVE first went to a pulp mill he knew the superintendent didn't want any chemists. He hadn't any use for theorists, he said. It was the same old story that the administrator of every one of these establishments would tell you if you asked for a post as chemist with them. STEVE took a job as a yard rustler, and despite the backache from unaccustomed work, he climbed around in his leisure and made tests and discovered not only shocking losses, but worked out plans whereby they might be completely avoided. He didn't talk until he was sure that what he had to say meant dividends. Then this yard rustler who was also a graduate chemical engineer opened up and the authorities had to listen. Did they listen because he was a graduate of Massachusetts Institute of Technology? Not on your life! And look at him today! He is one of the leading chemical engineers of the country, while some of his classmates are doubtless still making routine tests!

"If you start in as a dishwasher or a porter or a de-

livery clerk in any of those establishments I named and keep constantly using your head, never forgetting the chemical aspect of every problem that comes up, reading up the literature and corresponding with men who know more than you do, your chances are a hundred per cent better than those of any of the fellows who are trying to get through the open doors. If you are discouraged today with all the opportunities awaiting the man who looks for them, it is because you can't think for yourself, or because you won't. If you can't think for yourself, you'd better quit chemistry. If you merely lack the habit of thinking for yourself, it is time to acquire it. That is being born again!"

Signposts of Metallurgical Progress

IT IS perhaps trite to remark that Americans are prone to become provincial, and that a study of conditions abroad would do much to improve their perspective. Even so, we repeat that much the same forces are moving in industry both here and abroad—we may not be able to see them ourselves and at home, but we can discern them in the foreign situation, or can be told them by European visitors.

The French have long been noted for a peculiar excellence and artistry in their manufactured products, yet Professor CAVALIER, French exchange professor in the United States, in a statement on "Problems and Progress of Iron and Steel Metallurgy in France," written for the American Society of Mechanical Engineers, says:

The war, in bringing together for the national defense the industrialists and the men of science in the process of intensive production of metal, has powerfully contributed in France to the employment and to the diffusion of new and precise methods of work and of control. In the development of the use of scientific methods, the progress realized by systematic study in the laboratory usually penetrates slowly into industrial practice. Producers in the average industry have a tendency to consider the laboratory as a luxury which does not pay. Without doubt these good industrial habits which were acquired under the force of circumstances will continue. And thus the war will have contributed to the progress of our metallurgical industry, even though it be in a measure which only compensates to a slight extent for the great losses resulting from the destruction of our factories.

Here is a general statement of the advantage of science to industry—but sometimes "science" is little more than close observation and the application of common sense. A particular instance of this infusion of common sense into industry was noted some time ago in these columns—an instance drawn from some remarks of EUGÈNE SCHNEIDER, when he showed it to be possible to reduce large ingots to gun tubes in 11½ days and seven heatings, whereas 43 days and nine heatings were the usual allowance. Why build greater shops if the old ones can do this?

Lastly, an eminent European metallurgist recently in this country expressed to a party of friends his personal opinion that American metallurgical industry, especially in the East, was greatly overbuilt. "This being granted," he continued, "it is evident that there will be the keenest competition for the available business. Much of it will go to the lowest bidder, who ordinarily will have perfected his methods so that he can produce at an extraordinarily low price, but I am confident that a larger and larger proportion of the business will go to the people who can put quality into their product, as well as into their management and production methods."

The Railroad "Problem"

THE railroads are poor. There is no doubt about that, for the railroads themselves admit it. By this time it ought to be clear that the railroad "problem" is like the poor, in that we have it with us always. Who can remember a time when there was not a railroad "problem"? Back in the 1880's the problem was "rebating," etc., and how to stop it. In 1887 came the original interstate commerce act. Ever since it has been just one thing after another.

An outstanding feature of this practically continuous performance is that the issue has been so different at one time and another. For instance, there were certain periods before the war when nearly every business man, and nearly every business review, was saying that business would not be really good until the railroads were permitted to advance their rates. Of late the chorus has been shouting that business will not be good until rates are reduced.

Perhaps the explanation is that it is psychological. Railroads are a good thing and—what is more to the point—an easy thing to talk about. The railroads are almost ubiquitous. Everybody patronizes the railroads directly or indirectly. Then the stockholders and bondholders of the railroads are very numerous. Next, a couple million or so persons are employed by the railroads. Last, but by no means least, particularly when one judges by the amount of noise made, are those that sell or would like to sell to the railroads.

The railroad problem, or question, or subject of debate, has fallen in various categories. Sometimes it is said to be a political matter. At other times it is "an economic question," while at other times it is said to be just plain business. Other things may be important, but men do not feel themselves so directly interested nor do they have the same unbounded confidence in their ability to discuss them and to cite to the man buttonholed convincing facts if only the buttonhole will stand the strain.

Business is not as good as men would like to have it, and there is nothing more convenient on which to blame the condition than freight rates. There is a fine slogan: "Everything else has been liquidated—why not freight rates?" Then details are entered into. The railroads have not been earning the expected return on valuation, which is only 6 per cent, but if rates were reduced there would be more business and so the railroads would make more money after all.

The first freight blockade or congestion in the history of American railroading occurred in the winter of 1902-1903. In recent years such blockades have been frequent, and on each occasion it has been urged that we must have improved transportation facilities and the public can afford to pay for the improvement. The popular conception seems to be that light railroad earnings, an average of 2.6 per cent on valuation in the eight months January to August inclusive instead of the desired 6 per cent, are the evidence of traffic being light. The physical volume of traffic, however, is reported, the public paying little if any attention. In the first eight months of this year the ton-mileage was only 24 per cent under that in the same period of 1920, and 1920 was the record year for freight movement. Last August the ton-mileage was only 29 per cent under that of

August, 1920, the record month in all history for freight movement. The way is not as easy as is assumed for the railroads to obtain a large increase in business and handle the business satisfactorily.

Chicago Citizens Support Landis Award

PUBLIC sentiment on the labor union situation in Chicago has crystallized to a definite action which should be far reaching in its effect on all industry. One hundred and fifty business men and representative citizens have organized under direction of the Chamber of Commerce into a body known as the Citizens Committee to Enforce the Landis Award. It is to be a permanent organization with the purpose of bringing about 100 per cent adoption and enforcement of the terms and conditions laid down by Judge LANDIS in the building arbitration decision.

A statement issued at the first meeting on Nov. 10 shows that two months has elapsed since Judge LANDIS gave his award in the building controversy. Prior to that time Chicago for years paid tribute to dishonesty, graft and various forms of extortion, and conditions have grown more intolerable each year. Investors have hesitated to supply funds for building because of extravagant cost. Business expansion has halted because of excessive overhead. Industries have feared to take advantage of Chicago's natural facilities and market position because of the city's reputation based on conditions in the building trades.

In spite of the agreement of contractors and building trade unions to participate in the arbitration, some of the contractors and some of the unions have proceeded to work without regard for the award. Continuation of the present trend will place Chicago in an even worse condition than existed before. The real program of expansion and the relief so sorely needed will not occur.

The committee will make no fight on the trade unions as such. Those unions which in letter and spirit have accepted the Landis award and are working under it will have the support of the citizens. Those behaving otherwise will automatically lose the support of the public. Those contractors who have entered into agreements with unions outside of the award deserve neither the consideration nor the support of the public.

Thinking folks desirous of fair dealing for all branches of society carry the balance of power in the United States. When it becomes otherwise we are lost. They are slow to move, but once under way become irresistible. This is only one of many instances where a chamber of commerce with right ideals serves as an activator to facilitate public reaction. We believe this committee will succeed in its undertaking.

Pitiable End of A Russian Scientist

WE ARE informed by Colonel A. I. KRYNITZKY, an expatriated Russian at present on the staff of the Bureau of Standards, that the venerable Prof. TSCHERNOFF, international authority on metallurgy, has succumbed to privation. A letter from his younger son contains the information that the widow, Mme. A. N. TSCHERNOFF, and one of their daughters live at Petrograd, Sergievskaja St., No. 1, Apartment 1, under most miserable conditions.

Readers' Views and Comments

Classification of Research Activities

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am very appreciative of your letter of Nov. 3 containing copies of the two editorials which appeared in *CHEMICAL & METALLURGICAL ENGINEERING* Oct. 5 and 12, 1921, and which were prompted largely by the paper which I presented before the American Society for Steel Treating in Indianapolis.

No doubt the idea in the mind of the writer of the first editorial is the very laudable one of placing research on a high standard and excluding all that which is unworthy of the name. I am heartily in accord with him on this point and am inclosing a reprint of a paper entitled "The Methods of Research" which I presented before the Illuminating Engineering Society about nine years ago and which had for its object the discouraging of those many abortive efforts which are put forth in the name of research. Unfortunately, however, the editorial writer of your journal has, in my judgment, discriminated on the basis of the material of research rather than on that of the ideals and methods of research.

We may quarrel with regard to the extension of the meaning of the word research to include investigations in other than in pure science, but by the dominating power of common usage the term has taken on a wide significance. In view of the fact that this wide significance has been crystallized in the very name of the National Research Council it is unfortunate that a criticism of its use, such as that which was connoted in the editorial, should be made. In accordance with the accepted significance of the term, the investigation of the phenomena which underlie successful electric welding must be termed research equally with the investigation of the ultimate structure of the atom. I find that this apparent unwillingness to admit the extended use of the term is as evident in the second editorial as in the first.

I should like to add a further word of comment with respect to the second editorial. The writer apparently disregards the classification which I have suggested, by which pure scientific research is divided into "frontier research" and "intensive co-operative research." We are in agreement that frontier research should be carried on in universities and privately endowed laboratories. I am strongly of the opinion, however, that that which I have termed "intensive co-operative research"

is a legitimate and even a necessary function of industrial corporations.

Finally I should like to call attention to the fact that the classification given in the editorial is not correctly taken from my chart. There is one mistake of a fundamental character and one of relative unimportance. The former is the classification of Engineering under the general head of research. According to my chart Scientific Research and Engineering are to be distinguished, although under Engineering there is one link to research. The relatively unimportant error is that number 5, "Engineering Practice," has no part whatever with research and is, therefore, performed by corporation and private engineers and not "in corporation and private laboratories" as stated.

I am sending you the chart which served as the basis for my discussion.

I thank you for this opportunity of replying to the two editorials.

EDWARD P. HYDE.

Nela Research Laboratory,
Nela Park, Cleveland, Ohio.

Air Required in Baking Cores Made With Linseed Oil

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reading an article published in your issue of Oct. 26, 1921, on "Air Required in Baking Cores Made With Linseed Oil," by A. A. Grubb and U. S. Jamison, I note in the early part of the article a discussion of the amount of oxygen absorbed by linseed oil in drying, as well as the amount of hydrogen and carbon given off in the form of water and carbon dioxide.

The results of two investigations by Cloez and A. Genthe were quoted. Both of these authors had determined the increase in weight of the linseed oil, while Cloez had also determined the chemical composition of the linseed oil and the dry oil. Messrs. Grubb and Jamison draw conclusions from these results as to the total amount of oxygen which had been absorbed and the amount of carbon dioxide and water which had been given off.

Your authors apparently had overlooked the publication by myself and A. E. Ratner on this subject. The published report was entitled "The Decomposition of Linseed Oil During Drying" and was published in the report of the Eighth International Congress of Applied Chemistry, vol. 12, page 165.

An examination of this article will show that Mr. Ratner and myself in carrying out this investigation not only weighed the linseed oil before and after drying but also absorbed the carbon dioxide and water which were given off. We found that the oil, after 74 days, had increased 18.05 per cent in weight, while 14.55 per cent of water and 5.21 per cent of carbon dioxide had been given off. These figures show that 37.8 per cent of oxygen had been absorbed. These percentages were calculated on the weight of the linseed oil.

On comparison with the figures quoted by Grubb and Jamison, it will be noted that they find a much larger percentage of carbon having been given off and a much smaller percentage of hydrogen than are shown by our

CLASSIFICATION OF RESEARCH ACTIVITIES

figures. The calculation of the results published by Ratner and myself indicate that 1.42 per cent of the carbon was given off as carbon dioxide and 1.62 per cent of the hydrogen, calculated on the weight of the linseed oil. This is equivalent to 1.87 per cent of the carbon present in the oil and 14.73 per cent of the hydrogen. It may readily be that in the results given by Cloez the carbon percentage of the original oil was somewhat high, while the carbon percentage of the dried oil, as obtained by the analysis, may be low, the opposite being true of the hydrogen analysis. Unless the ultimate analysis was carried out with the greatest of care, there may be considerable error in the carbon and hydrogen determinations. On the other hand, the absorption of carbon dioxide and water as given off in the drying of linseed oil can be carried out with great accuracy. It also seems more reasonable that the hydrogen should be given off in larger quantity than the carbon in the drying of a substance like linseed oil.

Professor Chemical Engineering.

Facts and Fancies About the Oppau Explosion

To the Editor of Chemical & Metallurgical Engineering

SIR:—In recent issues of your journal, and in particular on pages 814-815 and 818-822 of the Nov. 2 issue, many different explanations of the recent disaster at Oppau have been discussed, and it has been concluded that no theory yet advanced can be regarded as more than speculative. The cause of the sudden decomposition of the 4,500 tons of ammonium sulphonitrate $(\text{NH}_4)_2\text{SO}_4 \cdot \text{NH}_4\text{NO}_3$ remains a mystery.

So far only *chemical* explanations have been adduced. It is very possible, however, as will be evident from what follows, that the primary cause of the explosion may have been of a purely *physical* nature.

Ammonium nitrate is a salt which exists in no fewer than six different crystalline modifications.¹ Five of these are stable at atmospheric pressure, each throughout a definite temperature interval only. The various transition points have been very carefully investigated², and it has been found that changes in crystal form, as the substance cools, occur at 125.2, 84.2, 32.1 and —18 deg. C. Each transformation is attended by considerable evolution of heat and by a considerable change in volume, in some cases positive (expansion) and in others negative (contraction).

The study of these transition points became a matter of practical importance during the Great War, when ammonium nitrate, mixed with TNT to give amatol, was used very extensively as a high explosive. Any change of state involving an increase in volume which might occur in a filled and sealed shell would, it is clear, constitute a grave source of danger, owing to the inevitable rupture of the shell. The time-honored experiment of bursting a bomb by filling it with water, screwing the fuse tight and leaving it out of doors on a cold winter night may be mentioned as a familiar, exactly analogous phenomenon.

Now the change of state which is most significant in the case of stores of ammonium nitrate is that which occurs at 32.1 deg. C. (89.8 deg. F.), since this temperature will very frequently be exceeded in summer. The transformation brought about by raising the temperature above 32.1 deg. C. resembles that induced by cooling water below 0 deg. in two respects—it is very

subject to delay and it is accompanied by a large increase in volume. The presence of other substances accentuates the tendency toward delayed transformation; it is quite possible to raise ammonium nitrate mixture to a temperature well above 32.1 deg. C. without immediate change of state occurring, just as it is possible to supercool water solutions without immediate appearance of ice. In such an event, however, the system will be like a cocked gun. Any disturbance of the metastable conditions will start a rapid change of state.

Is it not plausible that this is what took place at Oppau on the morning of Sept. 21? We are told that the temperature in the storehouse during the previous night was over 100 deg. F. Suppose transformation to have been delayed, and to begin suddenly at some point in the caked mass of ammonium sulphonitrate at such a temperature. It would spread rapidly through the entire 4,500 tons. The consequence would be a great increase in the volume of the material. At many places in the interior of the hard, rocky mass, tremendous pressures would be set up, which could be relieved only by explosive disintegration. This preliminary *physical* explosion might very conceivably be severe enough to induce a secondary *chemical* explosion throughout the entire mass, playing the part of the primer in the detonation of a high-explosive shell.

All this is, of course, like the other theories which have been put forward, merely speculative, but it constitutes a possibility which ought not to be left out of consideration. One of the first points for investigation should be the exact effect of ammonium sulphate (with which ammonium nitrate forms at 30 deg. two double salts, both unstable in water solution³) upon the transitions of ammonium nitrate. It is quite likely that the double salts formed also exist in more than one allotropic modification. As you have aptly stated in your editorial of Nov. 2, "an intensive study of the nature of ammonium nitrate and its mixtures may not explain all of the mysteries of the Oppau explosion, but it will do much to prevent the recurrence of similar disasters."

Explosion of Agitator Charged With Naphtha

To the Editor of Chemical & Metallurgical Engineering

SIR:—At a neighboring refinery an agitator charged with 50 deg. Bé. naphtha exploded recently without any apparent cause. The explosion occurred almost immediately after the agitator had been charged with approximately 900 bbl. of the naphtha. This oil had a temperature of about 70 deg. F. and was pumped up from the bottom through the chemicals, which consisted of litharge and caustic soda. The agitator has a capacity of about 2,100 bbl. and is not lead-lined. Electric light wiring was carried in conduit and it seems unlikely that a spark from this source may have been the cause. It is said a street car about 100 yd. distant passed by at the time of explosion, and, by a spark, may have ignited the light vapors which were carried in that direction. No strong wind prevailed at this time.

Will you please inquire if some of your readers or contributors can give a cause for this fire?

W. H. PAPE,

American Iron and Steel Institute

Varied Program of Technical Papers at the Twentieth General Meeting Included Furnace Design, Firebrick, a Direct Process for Steel Manufacture, Welding, Relation of Iron and Steel Industry to the Chemical Industry, and Steel Lumber

LAST Friday, Nov. 18, the American Iron and Steel Institute met for its twentieth general meeting in New York City, and was proud to entertain Marshal Foch. Over a year ago, when President Gary was in Paris, Marshal Foch expressed the desire to meet a representative gathering of men in the American steel industry. And so the steelmakers put on their holiday togs and forgot their business worries long enough to do honor to the leader of the allied armies.

The result was the largest banquet New York has ever seen—and who will say that men in the steel industry do not enjoy big things?—largest in point of numbers, and second to none in a genuinely enthusiastic and whole-hearted welcome to an admired friend. President Gary, William D. Guthrie and Charles M. Schwab ably expressed the sentiments of the assembled members and the industry they represent toward their honored guests. Mr. Schwab's talk was especially interesting, since it was the first public comment since the Disarmament Conference by the genial head of the greatest munition plant of the world, and he echoed the thoughts voiced by Mr. Gary in the morning.

"I would like to take advantage of this occasion to say something which has long been upon my heart, and which at this significant moment it is clearly my duty to say," said Mr. Schwab. "It was stated at some of the sessions of the recent League of Nations at Geneva, it has often been carelessly suggested in the press, that the flame of war is in great measure kept alive by those interested in the private building of naval ships and the manufacture of munitions of war.

"I can, of course, speak only for myself, but I believe I know and express the sentiments of others placed in positions similar to mine when I say this:

"If the armed protection of our country is necessary, the establishment of which I am the head will devote itself with all its energy to providing means for the protection of this country's homes and families. But I say to you from the bottom of my heart that if the statesmen now assembled in Washington, under the far-sighted leadership of our President and Secretary Hughes, should find it possible to bring about disarmament and permanent peace, gladly would I see the war-making machinery of the Bethlehem Steel Corporation sunk to the bottom of the ocean."

Morning Session

Judge Gary, as is the custom, opened the morning session with an address—not before the members had tendered him a hearty welcome, almost an ovation. After calling attention to statistics showing a steady improvement in American business during the autumn months, he warned his audience that it was yet impossible to predict when the world, or even this country, would return to normalcy. This he felt was due to high cost of living, the high cost of production and transportation and the high cost of earning and owning money, costs which were inflated for a variety of reasons, but which must be adjusted more nearly to their mutual

relations before the war. Judge Gary was inclined to blame the high cost of living largely to grasping middlemen handling food, clothing and shelter. Production and transportation costs were controlled by inflated labor rates and low performance in highly unionized trades. Lastly, taxes were so high that there was little incentive for the owner of money or property to put it to use and further extend his holdings. When these conditions would be corrected, he could not prophesy.

Enthusiastic applause marked his assertion that the industry confidently expected a sharp limitation of naval armament. Considerations as to tonnage lost to the steel industry were unworthy of notice. As a matter of fact, what could be better for business—either in steel or paper, wheat or textiles—than a world at peace?

TECHNICAL PAPERS

S. W. Miller, president of the American Welding Society, opened the technical session with an extensive paper on Fusion Welding. He discussed in detail the effects of oxygen and oxide in welds and in the plates to be welded—a matter which we hope to present in extenso later. The following properties of recommended metal should be interesting:

TABLE I. PROPERTIES OF WELDING MATERIALS

	Steel to Be Welded	Gas Welding Usual Welding Rod	Preferred Welding Rod ¹	Electric Welding Hard Drawn Rod ²
C.....	0.15 (max.)	0.06 to 0.10	0.20	0.15 to 0.18
Mn.....	0.30 to 0.60	0.15	0.40 to 0.60	0.40 to 0.60
S (max.).....	0.05	0.03	0.04	0.04
P (max.).....	0.04	0.03	0.04	0.04
Ni.....			3.25 to 3.75	
Tensile strength	50,000	52,000 (max.) ²	58,000 ²	60,000 ² (max.)
Yield point	30,000			
Elongation in 8 in., per cent, 30				
¹ Corresponds to S.A.E., specification 2320.				
² Strength of weld.				
³ Chemical analysis not so important as hardness, uniformity and high general quality.				

In order that tests may be of value, they should be executed on fairly large specimens and show the following data:

Chemical analysis of the wire. Chemical analysis of the base metal. Tensile strength and other characteristics of the base metal. Microstructure of the base metal. Microstructure of the welding wire or electrode. Tensile characteristics of the welded pieces. Bending characteristics of the welded pieces, hot and cold. Size of electrode or welding wire. Amount of wire used. Amperes during welding. Open circuit voltage. Welding voltage. Make of torch and size of tip. Gage pressure of oxygen and acetylene.

A cold bend test is extremely informative. Take a single V flush weld about 2 in. long, and bend it so the top of the V is stretched, measure the angle at fracture, and note what portion of the bend occurred in the weld and what portion in the plate.

WELDING OF CAST IRON

The welding of cast iron is easier than that of any other metal, and the results obtained are better, except possibly in case of cast aluminum, where the results are just as good. In welding cast iron any material

that is to be added should be of such a character that the application of heat will not burn out the carbon and silicon to such an extent as to make the weld difficult to machine. This means that it should contain a considerable proportion of silicon, this being the first constituent to disappear under the heat. Ordinary machine iron is entirely unsuitable for the purpose, and it is usual for a good cast-iron welding rod to contain at least 3 per cent of silicon. When this metal is melted into the weld, it produces a fine-grained structure lower in graphitic carbon than the material being welded, because it is applied in small quantities and cools rapidly. In gas welding of cast iron it is permissible to use a tip that is large in proportion to the size of the casting, blocking up the edges to keep the melted metal from running away. But in steel welding by gas, too large a tip will make the metal boil and foam, and is certain to injure the weld. A properly welded piece of cast iron will always break outside the weld. The principal difficulty in cast-iron welding is in taking care of the shrinkage or contraction, which of course cannot be avoided, although it can usually be allowed for by expanding other parts of the piece, or by setting the pieces farther apart than they were when broken. The proper methods to follow to avoid strain in the welded piece, due to expansion and contraction, require close attention and much experience on the part of the welder; and even with the greatest care cracks occur at times. It is quite possible that there will be heavy strain in the welded piece, which, however, will not be great enough to cause trouble until it is put in service, when the additional strain due to this may cause it to break. Chilled iron is readily welded, although, on account of its brittleness, the difficulties from expansion and contraction strains are increased when compared with gray iron. Malleable castings dare not be melted, and therefore are not capable of being welded, unless they can be annealed, which is usually impossible. It is therefore customary to join broken parts of malleable iron by using a manganese brass or a similar alloy, which will unite with the malleable iron at a temperature below its melting point. The joint so made is strong and ductile and answers every purpose. Of course, if the malleable iron be melted, it will revert to chilled iron and lose its strength and ductility. Even the use of manganese brass will to some extent change these properties, but not sufficiently to cause trouble in practice.

DIRECT PROCESS FOR STEEL MANUFACTURE

An interesting paper discussing a "Direct Process for Steel Manufacture" was presented by O. E. Bourcoud. After a brief review of the many previous and unsuccessful attempts, he says that solution of the problem depends upon, first, a method of producing large volumes of hot reducing gas of great purity from low-grade fuels (a matter discussed by him at length in *CHEMICAL & METALLURGICAL ENGINEERING*, April 6, 1921, under the title "Gasification of Powdered Coal"), and second, correct application of a stream of this gas to the ore to be reduced. The essential conditions surrounding the latter may be defined by a study of blast-furnace operations, which Mr. Bourcoud presents in a very interesting manner, showing that his resulting mathematical formulas for the reduction of hematite apply equally well to the 80-ton furnace described many years ago by Sir Lowthian Bell, and to the modern 500-ton Lackawanna furnace studied by H. H. Campbell. His formula shows that the time required to reduce a

spherical lump of ore to a given depth varies directly as the square of that depth, inversely as the percentage of reducing compounds in the gas and inversely as the square root of its velocity head. Using gas containing 45 per cent of active elements at an average temperature of 850 deg. C. and at a velocity of 9.1 m. per second, 480 seconds would be required to reduce an ore particle 1 mm. in diameter. If the particle be smelted in a rotary furnace and lie on top the charge 42 seconds in every hour, the ore would need to remain in the furnace 11.7 hours, and a 10-ton per hour furnace would need to be nearly 1,000 ft. long.

In order to reduce this evidently impracticable size, the author proposes to introduce spiral baffles in a 10-ft. rotary furnace, with a pitch of 2 m. forcing the gas to spin through in a whirlwind fashion, thus increasing the pressure head and increasing the amount of active gas from 7 per cent to 55 per cent of the total in the furnace. In such a furnace passing 62 cu.m. of gas per second at 850 deg. C., the mean velocity of gas in contact with the ore would be 33.9 m. per second, the angle of impact about 63 deg., and the normal pressure about 4 kg. per square meter. A grain of ore 3.4 mm. in diameter would be reduced in 140 seconds, and a 10-ton per hour furnace would be 75 m., or 250 ft., long.

The paper concludes with plans and estimates of a complete plant, consisting of proper gas producers, pre-heating (and nodulizing) furnaces, reduction furnaces, machines for compressing the hot sponge out of contact with air and charging directly into electric furnaces, where the metallic iron is melted and separated from any unreduced oxides, the latter forming a slag. Extensive tables showing the thermal balance and estimated (pre-war) costs of the operation are also appended.

J. M. Camp, director of the bureau of technical instruction, Carnegie Steel Co., then read a paper on the "Relations of the Iron and Steel Industries and the Chemical Industries," a paper which we shall print in a subsequent issue.

Afternoon Session

W. A. Hull, of the Bureau of Standards, recounted the work which has been done at that institution, at the Mellon Institute, and by leading refractory manufacturers, on the properties of firebricks. During the last 20 years various tests have been devised and reduced to a workable basis. However, there is still a great need of information on the actual conditions of service, information which the consumer should have in order to purchase his firebrick intelligently. It follows that specifications are largely influenced by the brick manufacturers, who describe in them something they can make cheaply and in quantity, whereas the specification should often call for something ideal for the purchaser, but at first little more than a mark for the producer to aim at.

"The question of price is one of the big stumbling blocks in the way of improvement. Not until the information gained by the production man and the metallurgist penetrates to the purchasing agent's sanctum in sufficient quantities to produce an effect can the refractories question be said to be on a fair way to a satisfactory solution."

Therefore, notwithstanding serious complaints by prominent metallurgists, Mr. Hull is of the opinion that the average product is unquestionably better than it

was 20 years ago. The eyes of the users have been opened to the fact that even the best brands do not run as uniform as they had been assumed to do, and defects that had formerly been counted of small consequence have been found to be vital factors in shortening the life of important installations. Some large metallurgical establishments are now making some of their own refractories, because their own efforts give vastly better results in special service than anything they are able to buy. American brick for byproduct coke ovens, and the recent successful application of silica refractories to limekilns and beehive ovens, are two achievements which indicate that firebrick makers can deliver an excellent product in large quantity when they have acquired the necessary information on what duty the brick must withstand.

OPEN-HEARTH PORTS

"Improvements in Port Construction in Open-Hearth Steel Furnaces" was discussed in a paper by John W. Kagarise, of the Edgar Thomson Works. Owing to the fact that flame temperatures are perilously near the softening point of furnace refractories, the shape and contour of the passages through the "block" were either built to oppose minimum resistance to the rush of hot gases, or the flame rapidly rendered them so. Only since the advent of successful water-cooling devices has it been possible to build ports on rational lines with reasonable assurance of permanence.

Experiments were made at the South Chicago Works in 1903, using a series of 1-in. pipes, one behind another reaching from front to back of furnace and bent so as to cool the two sides and top of the gas port mouth. By this means a life of 300 to 400 heats is now obtained. Clear water is not available in the Pittsburgh district, so the Duquesne plant developed the so-called Parks port. In this, the gas port arch is laid of 9-in. brick; then eleven 4-in. water pipes are laid side by side, and the arch finished by a 4½-in. brick cover. The water pipes reach from outside the block to within a foot of the mouth; a 1-in. pipe inside each discharges cooling water near the welded end. In case one of the pipes becomes plugged or is lost, it can easily be withdrawn and a new one inserted; 300 to 400 heats are obtained.

Welded steel plate water jackets have been successfully exploited by L. L. Knox, recent designs of the cross-port cooler extending from front to back of the furnace near the front of the port, and thus is very accessible when it is necessary to clean out sediment. The Lackawanna Steel Co. uses a so-called Blair port, which is a trough-like water jacket, which when inverted and properly set forms the complete side walls and arch of the gas port. Some early forms have been in use 6 years.

While operators now readily agree that some form of water cooling is indispensable, only recently have they turned their attention to a principle stated in 1912 by C. A. McCollum of the Homestead works: that well-mixed air and fuel should enter the furnace at high velocity through constricted openings, and waste gas leave at low speed through wide flues. In order to effect this, the Steel Co. of Canada has adopted the McKune system, and the Brier Hill Steel Co. the Egler furnace. Both these designs close the air uptakes on the incoming side with water-cooled valves. Air is blown through the checker chambers into a well and from there through the central port. Gas also enters the central port

through appropriate openings, and the mixture burns at the mouth much like a blow torch. At South Chicago, constriction at the incoming end is more simply effected by lowering water-cooled dampers through the roof, directly in front of the air ports, partially closing them and forcing the air to enter at the center of the furnace, cutting across the gas current. Such a furnace has made 106 heats each of 85.5 tons in a month, working on regular orders of steel ranging from 0.08 to 0.45 carbon. Charge was 53 per cent hot metal, 41 per cent scrap and 6 per cent ore. Coal consumed per ton was 348 lb. of 13,200 B.t.u. Kentucky coal.

"Venturi Line" furnaces have also been developed at South Chicago, so called from the fact that the arch above the ports dips sharply toward the bath, and the side walls also bulge inward, thus giving internal lines roughly like a Venturi meter. These restricted openings, a gas port mouth set back about 3 ft. from the neck, and induced draft from a waste heat boiler installation have given thorough mixing of air and fuel and good flame control. Combined with side dampers, this type of furnace gave the remarkable tonnage noted.

Various modifications of these systems are necessary when the fuel is changed from producer gas to natural gas, to pulverized coal, to byproduct oven gas, or to tar. Byproduct gas has given some trouble owing to its non-luminous flame; tar has been introduced to cure this defect, but it has been found at Duquesne that if a small quantity of air be burned in the gas as it enters the furnace, the luminosity of the flame can be controlled at will.

Conditions in Swedish Iron Industry

Reports submitted at a recent meeting of the Swedish Iron Works Association show that during the second quarter of this year but twenty of the 134 blast furnaces have been running, and only a few of the steel plants have been kept going on very short time, reports Consul General Murphy of Stockholm in *Commerce Reports*.

SIX MONTHS' IMPORTS AND EXPORTS OF IRON AND STEEL

January-June	Exports Tons	Imports Tons	January-June	Exports Tons	Imports Tons
1914.....	189,500	137,200	1918.....	200,300	51,400
1915.....	238,600	103,500	1919.....	129,600	33,700
1916.....	276,000	163,300	1920.....	134,400	110,300
1917.....	244,500	43,500	1921.....	61,300	71,300

In the first seven months of 1920 the export of iron ore amounted to 1,900,000 tons, while the export for the corresponding period of the present year amounted to 2,560,000 tons—an increase of 660,000 tons.

At the end of July, 1920, out of the 131 blast furnaces in Sweden, but 66 were running and of the 203 Lancashire hearths but 84 were operating. At the time mentioned there were likewise but 12 of the 18 bessemer, 41 of the 77 Martin furnaces, 4 of the 20 electrical steel furnaces partially in operation. At the end of July of this year the situation was still worse—i.e., 20 blast furnaces, 49 Lancashire hearths, 6 bessemer, 17 Martin and 5 electrical steel furnaces were running.

The production of pig iron in the first seven months of this year amounted to 225,600 tons, against 249,500 tons in the corresponding period of last year; blooms, 13,800 tons, against 31,300 tons; bessemer ingots 15,400 tons, against 26,600 tons; and Martin ingots, 96,500 tons, against 200,600 tons in January-July of 1920. rolled and forged iron and steel were manufactured to the extent of 63,600 tons, against 173,400 tons.

Sulphate-Free Sulphites for Standard Sulphur Dioxide Solutions

BY S. LANTZ SHENEFIELD, FRANK C. VILBRANDT AND JAMES R. WITHROW

THIS paper points out: (1) The doubtful validity of all previous work based on the use of sodium sulphite as a standard in sulphur dioxide investigations; (2) the inability to prepare sodium sulphite free from sulphate according to manipulation details in the literature; (3) the difficulties encountered in preparing pure moist sodium and calcium sulphites and their subsequent oxidation during drying.

The question of SO_2 fumes from chemical as well as smelter plants is of constant interest. Simplification of the methods for SO_2 determination naturally demands attention. Important and acceptable as the iodine method for the determination of SO_2 may be, there has always been a demand for an alternative method, and, if possible, one based on a more stable standard titrating solution. The use of potassium permanganate has been investigated repeatedly for this reason. This laboratory became interested in this latter method to reduce the cumbersomeness of the field test when the iodine method is used.

UNRELIABILITY OF SODIUM SULPHATE AS STANDARD

In any important investigation it is fundamentally desirable, if possible, to use as a standard the actual material to be investigated, if the latter can be got into condition of known concentration. In the analytical study on pollution of the atmosphere by fumes from smelters many chemists have encountered great difficulty in the evaluation of methods of determining the SO_2 content because they have accepted statements in the literature with respect to the reliability of sodium sulphite as a standard in the study of SO_2 pollution. The danger from accepting such statements is not always realized, thereby leading to erroneous conclusions regarding certain analytical methods of evaluating SO_2 , sulphurous acid or sulphites.

This work endeavors to prove the unreliability of accepting sodium sulphite as such a standard. It is shown how far the preparation of sulphate-free sulphite can be accomplished when the product is recrystallized or dried, and also the possibility of obtaining such a product in the freshly prepared moist condition.

The use of sulphites for standardizing permanganate solutions would eliminate a host of troubles which occur in the analysis of a mixture of gases containing a water-soluble component such as sulphur dioxide. Quite naturally, therefore, sulphites have been used by previous workers for standardization in the comparison of the permanganate and iodine methods [Lunge and Smith, *J. Soc. Chem. Ind.*, vol. 2, p. 460 (1883); Lunge and Segaller, *ibid.*, vol. 19, p. 222 (1900); Pinnow, *Z. anal. Chem.*, vol. 43, p. 91 (1904); and Millbauer, *Z. anal. Chem.*, vol. 48, p. 17 (1909)], and also directly as a standard in iodimetry [Giles and Shearer, *J. Soc. Chem. Ind.*, vol. 3, p. 197 (1884); Volhard, *Ann.*, vol. 242, p. 101 (1887); Richardson and Aykroyd, *J. Soc. Chem. Ind.*, vol. 15, p. 172 (1896); and Ferguson, *J. Amer. Chem. Soc.*, vol. 39, p. 364 (1917)] and for testing the applicability of the permanganate method [Honig and Zatzek, *Monatsh.*, vol. 4, p. 738 (1895); Dymond and Hughes, *J. Chem. Soc.*, vol. 71, p. 314 (1897); and Sweeney, Outcault and Withrow, *J. Ind. Eng.*

Chem., vol. 9, p. 949 (1917)]¹ for sulphur dioxide, sulphurous acid and sulphite determinations.

In continuing an investigation started in this laboratory on sulphur dioxide fume from sulphuric acid plants, irregularities of unknown origin were found in a previously published paper on the subject from this laboratory (Sweeney, Outcault and Withrow, *loc. cit.*). An effort had been made therein to use sodium sulphite as a standard of known concentration of SO_2 . Preliminary gravimetric analyses of this substance disclosed variable sulphite composition and the constant presence of sulphates by qualitative tests with barium chloride in acid solution. It was then found in a review of the literature that in all cases therein where sulphate-free sulphites were claimed to have been prepared mention is omitted of any qualitative test used to demonstrate this. It seems to have been *assumed* that recrystallization eliminated the sulphates. This raises grave doubts as to the validity of all previous work on the use of sulphites as standards, except in those cases where rigorous quantitative examination was frequently made upon the sulphite. We have therefore undertaken the preparation of sulphate-free sulphites to determine the actual occurrence of sulphate contamination with various preparation precautions.

OXIDATION OF SODIUM SULPHITE

The oxidation, upon standing, of Na_2SO_3 in the hydrated and anhydrous forms and in solution has been a matter of debate in the literature. It is claimed by some that it is stable under one or another of these conditions while others claim to have proved its instability [Davies, *J. Soc. Chem. Ind.*, vol. 1, p. 88 (1882); Giles and Shearer, *loc. cit.*; Reese, *Chem. News*, vol. 50, p. 219 (1884); Bothamley, *Am. J. Pharm.*, vol. 62, p. 520 (1890); Bigelow, *Z. phys. Chem.*, vol. 26, p. 493 (1898); Griffin, *J. Soc. Chem. Ind.*, vol. 19, p. 321 (1900); Young, *J. Amer. Chem. Soc.*, vol. 24, p. 314 (1902); Pinnow, *loc. cit.*; Lumiere and Seyewitz, *Z. angew. Chem.*, p. 784 (1904); Kastle and Elvolve, *J. Inf. Dis.*, vol. 6, p. 619 (1909); Hartley and Barret, *J. Chem. Soc.*, vol. 95, Tr., p. 1178 (1909); Elvolve, *Am. J. Pharm.*, vol. 82, p. 211 (1910); Foerster, *Arbb. Kais. Gesundh. Amt.*, vol. 49, p. 468 (1914); *Centralb.*, 1915, i, p. 447, and Haller, *J. Soc. Chem. Ind.*, vol. 38, p. 54 (1919)].

The irregularities of the reaction of KMnO_4 solutions on sulphites when the percentage recovery of SO_2 is found by the KMnO_4 method has been studied by Honig and Zatzek (*loc. cit.*, p. 746); Raschig [*Z. angew. Chem.* (1904) p. 580]; Pinnow [*loc. cit.*]; Day and Baker [*Analyst*, vol. 37, p. 439 (1912)], and Craig [*J. Soc. Chem. Ind.*, vol. 38, p. 96 (1919)].

The need for stabilization of sulphite solutions is also keenly recognized in the medical profession. The conclusions obtained in this field by various workers is that organic bodies in general are inhibitors of oxidation of sulphite solutions. [Foerscher, *J. Prakt. Chem.*, vol. 37, p. 27 (1846); Bigelow, *loc. cit.*; Young, *loc. cit.*; Titoff, *Z. phys. Chem.*, vol. 45, p. 641 (1904); Ruff and Jeroch, *Ber.*, vol. 48, p. 499 (1905); Baker and Day, *J. Soc. Chem. Ind.*, vol. 31, p. 1048

¹Correction—The former article on SO_2 by Sweeney, Outcault and Withrow (*loc. cit.*) from this laboratory credits the Selby Smelter Commission (U. S. Bureau of Mines Bull. 98 and Dymond and Hughes, *loc. cit.*) with using sodium sulphite as a basis for standardization and study. A subsequent correction [*J. Ind. Eng. Chem.*, vol. 9, p. 1148 (1917)] requests omission of this statement. Nevertheless, Dymond and Hughes actually depended on Na_2SO_3 as such a basis, though the Selby Smelter Commission did not do so.

(1912); Pinnow, *loc. cit.*; Sauillard, *Compt. rend.*, vol. 160, p. 318 (1915); Matthews and Weeks, *J. Am. Chem. Soc.*, vol. 39, p. 635 (1917); and Haller, *loc. cit.*] A general review of the literature on the substitution of other sulphites for the sodium salt reveals the fact that other sulphites are equally or more difficult to prepare pure. [Seuber and Elton, *Z. anorg. Chem.*, vol. 4, p. 44 (1893); Demmer, *Das Chemische Technologie*, vol. 1, p. 116 (1895); Griffin, *loc. cit.*; Weston and Jeffries, *Chem. News*, vol. 97, p. 85 (1908); Alexander, *Z. anal. Chem.*, vol. 48, p. 31 (1909); Henderson and Weiser, *J. Am. Chem. Soc.*, vol. 35, p. 239 (1913), and Abegg, *Handbuch der Anorganische Chemie* (1908).]

Whenever we attempted to use commercial sodium sulphite, unsatisfactory results were obtained in spite of all precautionary measures, and purification methods, such as the use of air-free water, repeated crystallization and centrifuging. The synthetic preparation of sodium sulphite was therefore undertaken. After unsatisfactory efforts with SO_2 and NaOH , carrying on all the operations in the absence of air, Na_2CO_3 was used. The apparatus consisted of a train for washing SO_2 from a cylinder through FeSO_4 solution for absorbing any oxidizing gases, BaCl_2 in HCl solution for precipitating any sulphates, water for absorption of spray from the previous wash bottles, saturated Na_2CO_3 solution for sulphite preparation and a Na_2CO_3 trap solution to prevent back suction of air into apparatus or the escape of SO_2 into the air.

The water and sodium carbonate solutions used were both sulphate and air free. After absorption of SO_2 in the Na_2CO_3 solution to form NaHSO_3 , an equivalent amount of Na_2CO_3 in solution was added and the evolved CO_2 was swept out with pure N_2 from a gasometer after passing through alkaline pyrogallate. The solution was then cooled to 0 deg. C. The fine crystal meal separating was filtered without removal from the apparatus by technique similar to that used by Hartley and Barret (*loc. cit.*)

For drying the hepta-hydrate a modification of the customary two-piece desiccator was used. The drying agent was 96 per cent H_2SO_4 and sodium pyrogallate solution was the oxygen absorbent.

RESULTS

The damp $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ upon being put in the desiccator gave not the slightest test for sulphates with BaCl_2 . The same was true of the mother liquor taken from the salt. In spite of the precautionary measures taken to prevent oxidation or leakage of air into the apparatus, some oxidation did subsequently take place; after one week of standing the product analyzed 7.52 per cent $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ and 88.7 per cent $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ with about 3.78 per cent excess moisture. The quantity of surface exposed on crystals of sodium sulphite is naturally enormously great compared with a solution of the salt, so that one naturally expects a more ready oxidation on moist crystals than one would in a concentrated solution which Lumiere and Seyewitz (*loc. cit.*) claim is stable.

An investigation was started to see if any other sulphite could be prepared in a more stable form. Calcium sulphite can be used as readily as sodium sulphite as a gravimetric standard for SO_2 . Since calcium sulphite is about forty-six times as insoluble as calcium sulphate at 18 deg. C., it was believed that any sulphate present in calcium sulphite could be readily washed out. This

was attempted and proved to be the case, for no sulphates were present on the wet or moist product. This fact also indicates that since sulphates were originally present and could be washed out, the sulphate contamination was not due to adsorption. Precautionary measures used in drying proved of no avail, for in all cases the dry sulphite was contaminated with sulphates produced by oxidation during the drying. It was felt, therefore, that calcium sulphite preparation offered no advantages over sodium sulphite.

ORIGIN OF THE SULPHATE CONTAMINATION

The sulphate found by the qualitative test with BaCl_2 resulted undoubtedly from oxidation of the sulphite. Such oxidation could occur in one of two ways. It might have resulted from leakage of air into the apparatus or from auto-oxidation of the sulphites themselves. In this work the apparatus, method and precautions used to exclude air leakage during preparation and drying were all that possibly could be expected.

It seems clear therefore that the preparation of sulphate-free sulphites for standard sulphur dioxide solutions is so difficult (if not impossible) that all work heretofore based upon such use of sulphites is of questionable validity.

While unsuspected air leakage could always be a possibility, nevertheless the precautions taken forced the conclusion that some form of auto-oxidation was really responsible for the sulphate contamination. Some of the sodium sulphite could conceivably oxidize other portions, being itself reduced to various possible derivatives, for Jungfleisch and Brunel [*Compt. rend.*, vol. 156, p. 1719 (1913)] have shown that $3\text{SO}_2 + 2\text{H}_2\text{O} \rightarrow \text{S} + 2\text{H}_2\text{SO}_4$. As our object was an effort to confirm, if possible, the literature claims that a sulphate-free sulphite was readily preparable, we did not stop at this time to investigate the interesting and complicated fields which, it is well known, auto-oxidation presents among the sulphur acids.

A sample of dry $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$, chemically pure, was tested for stability and showed an increasing amount of oxidation on standing. From an initial analysis of 89.61 per cent $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ by gravimetric analysis, it dropped to an average of 68.5 per cent two months later. Therefore the use of sodium sulphite heptahydrate as a weighable gravimetric standard in itself appears to be wholly unsatisfactory in refined work because of the necessity of its frequent analysis. To investigate the influence of manipulation details on the variation errors, a study was made of the influence of time of standing in solution before completion of the analysis. It was found that when air-free water was used for dissolving the sodium sulphite the purity of $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ as determined by the iodine method dropped from 88.5 per cent when solution stood 5 minutes before completion of analysis to 87.2 per cent after a 15-minute period and to 84.6 per cent when the solution was allowed to stand 40 minutes. In each of the above cases HCl was added to the iodine solution so that any oxidation that took place occurred within the Na_2SO_3 solution and the difference was not due to loss of SO_2 on standing as an acidified sulphite solution. This demonstrates that dilute Na_2SO_3 solutions are unstable in the presence of air, the extent of oxidation being a function of the time the solutions were in contact with the air.

The conclusions reached are:

1. All statements in the literature concerning the

preparation of sulphate-free sodium sulphite should be seriously questioned.

2. The validity of all investigations in the literature based upon the use of the prepared sodium sulphite as a sulphur dioxide standard is doubtful.

3. The inability to prepare sulphate-free sulphite for use as an SO_2 standard solution according to directions given in the literature has been shown.

4. Due to the rapid oxidation of sodium sulphite solutions in the presence of air, if for no other reason, this use of the substance for standardization of oxidation solutions is objectionable.

5. No method tried by us gave a dry $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ free of SO_4 when tested by BaCl_2 and HCl , notwithstanding claims in the literature that "pure sulphites" or " SO_4 -free sulphite" could be prepared.

6. A sulphate-free sodium sulphite heptahydrate and also calcium sulphite can be prepared moist.

7. Drying of sodium sulphite and calcium sulphite contaminated the product by oxidation.

8. This sulphate contamination is not due to adsorption of sulphates on sulphite.

9. Moist sulphites, all sodium sulphite solutions, and particularly dilute solutions, oxidize rapidly in air.

10. A recrystallization process, if carried on in the presence of air, will not give a sulphate-free product on account of this rapid oxidation.

11. Dry $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ is not stable toward oxidation in the air.

12. The production of sulphate-free calcium sulphite presents the same difficulties as does sodium sulphite.

Concentrated HCl as Metallographic Etching Reagent for Nickel

BY HENRY S. RAWDON* AND MARJORIE G. LORENTZ*

NICKEL and the nickel-rich alloys are usually classed among the best of the non-corrodible materials in common industrial use. Since they are so inactive chemically, they are etched for microstructural examinations with very considerable difficulty as a rule. Very active reagents, such as nitric acid or an acid to which a strong oxidizing agent has been added, are required. When etched with such solutions, pitting of the surface is apt to be excessive, and this is often the most conspicuous feature of the microstructure revealed. Another point, which is usually a disadvantage, is the plain etch-pattern produced lacking in contrast. Only the grain boundaries are revealed and none of the grains has any "individuality."

It is the purpose of this note briefly to refer to the use of concentrated hydrochloric acid as a metallographic etching reagent for nickel as having some very desirable features which most of the other reagents lack. The use of concentrated hydrochloric acid for this purpose was developed during the general study of etching reagents now in progress at the Bureau of Standards.¹

In the accompanying micrographs the character of

RESULTS OBTAINED WITH CONCENTRATED HYDROCHLORIC ACID AS ETCHING REAGENT

Material Etched	Etching Period	Results
Elec. nickel	1 hour	No action
Cast nickel	1 hour	Excellent contrast
Drawn nickel	1 hour	Excellent contrast
Rolled nickel	1 hour	Excellent contrast
Cast Monel	1 hour	Excellent contrast
Hot-rolled Monel	1 hour	Excellent contrast
Cold-drawn Monel	1 hour	Excellent contrast
Nickel sheet	1 hour	Excellent contrast
Elec. nickel melted and cooled in vacuo	2 hours	Poor; no contrast
Cast cupronickel (45 per cent Ni)	1 hour	Excellent contrast
Cast cupronickel (28 per cent Ni)	15 min.	Fair; no contrast
Rolled cupronickel (20 per cent Ni)	20 min.	Fair contrast
Manganese nickel (3 per cent Ni)	1 hour	Excellent contrast
Annealed nickel-brass (26 per cent Ni)	30 min.	Fair contrast
Annealed nickel-brass (17 per cent Ni)	30 min.	Fair contrast
Cold-rolled nickel-brass (17 per cent Ni)	15 min.	Poor contrast
Nickel-brass (5 per cent Ni)	15 min.	Poor contrast

the results which may be obtained by its use is illustrated; for comparison, there is shown also the structure as revealed by one of the common reagents. One of the best of these has been described by Merica² and consists of 50 per cent concentrated nitric acid, glacial acetic acid, 25 per cent, and water, 25 per cent; the proportions may be varied somewhat, however. The marked contrast and absence of pitting in the structures as revealed by etching with hydrochloric acid are very evident. One feature which appears to be the principal disadvantage in this use of hydrochloric acid is the long etching period required. As shown in the accompanying table, it was often necessary to keep the specimen immersed in the acid for 1 hour or more.

The results summarized in the table show that the general effect of concentrated hydrochloric acid is a contrast etch pattern. The best results by far were obtained with nickel and with alloy of high-nickel content. With alloys in which copper forms a considerable percentage of the composition, the results obtained were decidedly inferior to those with the high-nickel specimens. Micrographs showing the appearance of the microstructure as revealed by concentrated hydro-

chloric acid and by the acetic acid solution of nitric acid are given for the following materials:

Cast nickel (Ni, 99.3 per cent; Cu, 0.13; Fe, 0.25; C, 0.10; Si, 0.05).

Manganese-nickel (Ni, 97 per cent; Mn, 3).

Cold-rolled nickel sheet (Ni, 99.1 per cent; Cu, 0.35; Fe, 0.40; Mn, 0.05; C, 0.03; Si, 0.08).

Cast Monel metal (Ni, 66.3 per cent; Cu, 28.5; Fe, 2.49; Mn, 1.85; C, 0.12; Si, 0.73).

Hot-rolled Monel metal (Ni, 66.6 per cent; Cu, 29.3; Fe, 1.90; Mn, 1.76; C, 0.13; Si, 0.18).

Results obtained with ferric chloride as an etching reagent are somewhat similar for some of the materials to those described for hydrochloric acid. However, pitting of the surface was usually found to be rather pronounced and the nice gradations of light and shade were lacking. With oxidizing reagents such as H_2SO_4 and H_2O_2 , the appearance of the etched specimen was in all cases inferior to that produced by the nitric acid solution illustrated in the micrographs, and the pitting of the material was, in most cases, very pronounced.

FIG. 3. MICROSTRUCTURE OF CAST ALUMINUM-BRONZE (8 PER CENT AL). $\times 85$
Etching reagent, concentrated hydrochloric acid, 15 minutes.

The action of the reagent upon the common copper alloys was also examined. With bronze and aluminum-bronze results were obtained which were equal to those given by the usual reagents. Fig. 3 shows the results obtained with a cast aluminum-bronze (8 per cent Al), an alloy which is etched satisfactorily with considerable difficulty. For most of the common copper alloys, however, superior results can be obtained much more easily with the reagents usually employed.

New Chemistry Building at Iowa City

Prof. Edward Bartow, head of the department of chemistry at the State University of Iowa, in a recent address outlined the plans for the new chemistry building which is being erected at Iowa City. An initial appropriation of \$400,000 has been made for commencing the construction of the 6-story building which, when completed, is to occupy an entire city block. It is to include a central structure facing the east with three wings extending to the north and south. The main lecture room or auditorium will be located in the central structure on the east side of the building. On the lower level there will be two entrances to the room, which will enable it to be filled or cleared without delay—a desirable feature in changing classes. Back of the main lecture room there will be a preparation room which will also serve the smaller lecture rooms.

The library, furnishing shelf room for 40,000 books and table room for 200 students, is to be placed above the main lecture room and will be easily accessible both from the street and from all parts of the building.

The storerooms will be located in the geographical center of the block, one on each floor. The storeroom on the lower floor will be devoted to reception of supplies, that on the second floor to general storage, on the third, fourth, fifth and sixth floors to delivery rooms for the laboratories. On the sixth floor connection will be made through a corridor to the laboratories located on the east front.

With rooms for general utility, such as the storerooms, lecture rooms and library, in this central portion of the building, access to them from laboratories in the wings will be easy. This plan for the building was chosen rather than that of a hollow square because it makes it possible to reach any part of the building through corridors rather than through laboratories; the distances between the laboratories and general utility rooms are reduced to a minimum, and part of the building can be constructed now and wings to complete the building can be added later without interfering with the part already constructed.

Ground was broken on the southeast corner of the city block on August 9, 1921. Approximately one-half of the central structure and two of the wings are to be built immediately. In accordance with the general plan, wings may be added to the part under construction in any one or all of three places.

Each wing will contain four floors, 57 ft. wide and 81 ft. long, with light on three sides. This space can be used as a whole or divided into smaller rooms. Small laboratories, offices and special rooms can be cut off from either end of these wings and others will be placed along the corridors and on the second, third and fourth floors of the storeroom unit. Special rooms of this type are needed for instructors and for advanced students. Seminar room in which special reference books can be placed have been provided in the central portion.

Importance of the Olefine Gases and Their Derivatives

II—Diethyl Sulphate*

**Diethyl Sulphate of High Purity Can Be Prepared From Pure Ethylene and Sulphuric Acid—
Advantages as an Ethylating Agent: Low Volatility, Which Obviates Use of Autoclaves;
High Reaction Intensity; It Is Non-Toxic, Non-Flammable and Non-Corrosive**

By G. O. CURME, JR., AND H. R. CURME

IN A consideration of the many possible derivatives of ethylene, aside from those best known as a result of numerous recent publications, diethyl sulphate ("ethyl sulphate") is deserving of especial attention. It recommends itself particularly on account of the improvement it offers in many old and long-established processes, and also on account of the new fields of chemical operation which it promises to develop. As is generally known, the homologous dimethyl sulphate has already been widely used for purposes of introducing the methyl group, and apparently for no reason other than its more general commercial availability has progressed relatively much further in its field than has the diethyl sulphate in the field of ethylation. That this has been done commercially in spite of an average price high in proportion to the value of the methyl groups contained is indeed a tribute to the smoothness of reaction which characterizes the alkylation by means of the alkyl sulphates. Now that the diethyl sulphate is available in even more abundant quantities, it may confidently be expected that its use will also expand.

The preparation and isolation of diethyl sulphate, $(C_2H_5)_2SO_4$, itself is not a new accomplishment, as this material was described by Wetherill¹ in 1848 as a product of the interaction of sulphur trioxide on absolute ether. It is, when pure, a colorless liquid, with a pleasant though faint ethereal odor. It boils without decomposition at 96 deg. C. at 15 mm. pressure, and at 120.5 deg. C. at 45 mm. At temperatures above 140 deg. C. it begins to decompose slowly, and at 208 deg. C. it boils with considerable decomposition—the true boiling point probably lies several degrees higher. It has the density $D_{20}^{20} = 1.1837$.² On cooling it forms crystals which melt at -24.5 deg. C. This liquid is entirely neutral in reaction. It is not miscible with cold water; with warm water it is slowly hydrolyzed, and on boiling it yields eventually two molecules of ethyl alcohol and one of sulphuric acid. Diethyl sulphate is not flammable.

Since its discovery numerous investigators have studied it and have worked with it in a variety of ways. From the first it has been recognized as an ethylation agent of marked value, although in all hands it has not met with the same success. For instance, Lassar-Cohn³ states that in his experience it has not given satisfactory results, and yet Weyl⁴ a few years later

says, "Diethyl sulphate has attained great significance for ethylation." This difference in results may well be due to any of several causes, as the earlier experimenters may have had impure samples at their disposal. Their experience with the dimethyl sulphate may have led them to follow methods worked out for its use too closely, or indeed with a limited supply available the tests may have been carried out improperly. In any event positive evidence has since shown the value of this reagent and to the writers' knowledge in certain industrial processes it is being used today with commercial yields approaching the theoretical.

COMMERCIAL PRODUCTION

Only within the last twenty years have there been attempts to utilize diethyl sulphate commercially, and these attempts have been put under the difficulty of having a rather expensive source of material. In 1902 E. Merck⁵ obtained a patent on the production of diethyl sulphate by the vacuum distillation of the product obtained by mixing ethyl alcohol and sulphur trioxide. Later patents⁶ have proposed the production by means of the dry distillation in vacuo of sodium ethyl sulphate, and further by the interaction of chlorosulphonic acid and absolute ether.⁷ In all of these processes the initial product is highly impure and requires extensive after-treatment to obtain a commercially satisfactory product. Also the yields are rather poor, being in general less than 50 per cent of that demanded by theory. In the work carried on under the writers' direction, it was observed that the expense of using anhydrous materials, or vacuum distillations, could be avoided by using, instead of alcohol, the product of its dehydration—namely, ethylene. It was found that with pure ethylene and commercial sulphuric acid (66 deg. Bé.) a continuous cycle could be established producing high purity diethyl sulphate directly.⁸ The material from this source is now commercially available, and is finding a variety of technical applications.

ONLY ORDINARY PRECAUTIONS REQUIRED IN HANDLING

In the case of the homologous dimethyl sulphate a toxic effect from handling the material and inhaling its vapors has been noted and described by Weber.⁹ In this same report it is stated that the acute inflammation characteristic of dimethyl sulphate is not noted at all with the diethyl sulphate, and only the general action on the central nervous system is observed. From

a hygienic standpoint, diethyl sulphate is no more dangerous to handle than organic liquids such as aniline, benzene, etc. It has been the writers' experience, as well as that of others who have used this material on a large scale, that, observing only the most usual precautions against inhalation of the fumes of the heated material, it is possible for workmen to handle diethyl sulphate continuously without any evil effects whatsoever. It has been stated erroneously in previous publications that the toxic effect of the dimethyl sulphate is also characteristic of the diethyl sulphate. Accordingly, in order not to limit the usefulness of this reagent, it is well to correct this error which has gained admission to the literature. It is also worthy of attention that the toxicity of the dimethyl sulphate itself has been overemphasized, as has recently been pointed out by Mueller.¹⁰ Undoubtedly, a closer knowledge of such substances will provide a safe working procedure that also permits the full utilization of their valuable properties.

ADVANTAGES AS ETHYLATING AGENT

By means of this commercially new reagent it is possible to accomplish, almost without exception, the ethylation of any material which has heretofore been ethylated by any means whatsoever. Moreover, this ethylation may be brought about in plant operation with greater ease and simplicity than heretofore possible. Owing to its low volatility (b.p. 208 deg. C.), it is not necessary to use autoclaves for carrying on such reactions; any closed vessel fitted with a simple reflux and operating at atmospheric pressure will suffice. Also, as this reagent is quite neutral and is commonly used under neutral or alkaline conditions, a wider choice of materials for construction of equipment is possible than in many ethylations where strong acids are present. The material is non-flammable and therefore avoids any fire risk in its use.

In comparison with ethylation by means of ethyl bromide, the use of diethyl sulphate recommends itself both on grounds of simplified procedure, as well as economy of operation. In addition to avoiding the use of an autoclave, as above mentioned, the losses, in handling and storing of a volatile material, are eliminated, and the troublesome necessity for working over the bromine residues is entirely avoided. All of the value of the ethyl sulphate lies in the ethyl groups and the sulphate radical in most cases is not worth recovery.

A further important advantage, particularly in the case of diethyl sulphate derived from ethylene, is that only the purest ethyl derivatives are formed, containing no trace of homologous methyl or propyl compounds. Commercially this is equivalent to the use of tax-paid alcohol derivatives, although, of course, no alcohol is used in the production of the products.

GENERAL CONDITIONS FOR USE

The conditions under which reaction proceeds most smoothly are, of course, different in each separate case. However, in general, it is desirable to operate in the absence of water, if possible, as was suggested by Ullmann¹¹ for such alkylations as early as 1902. With diethyl sulphate it is generally desirable to use a slightly higher temperature than with dimethyl sulphate in order to get a similar velocity of reaction; but otherwise conditions are similar. Some reactions,

such as in the ethylation of aniline, need no heating whatsoever, but warm up from room temperature so as to need cooling. In most cases at temperatures between 100 and 125 deg. C. the reaction is quite rapid, and at temperatures above that it is possible that the reaction will become too violent. In all cases by controlling the temperature, or both temperature and rate of addition of the reagent, it is possible to maintain any desired rate of reaction. Frequently it is desirable to mix the finely powdered—if solid—material to be ethylated with the diethyl sulphate and then to heat the charge gently until reaction is complete. In other cases an inert anhydrous solvent, such as benzene or solvent naphtha, gives excellent results. As the reagent is miscible in all proportions with most organic liquids, the reaction can be brought about by simple admixture, in the case of ethylating a liquid. Usually the previous formation of the sodium salt of a material to be ethylated is desirable when such can easily be done, and in other cases the presence of an equivalent amount of caustic soda is desirable to prevent the formation of free acid.

Under the general conditions just described it is usually possible to get a great intensity of ethylation with the first of the two ethyl groups and a practically theoretical yield, both reckoned on this ethyl group and on the other material. The second ethyl group reacts exactly as the ethyl group of sodium ethyl sulphate and consequently with less intensity. With some reactions, such as the production of volatile ethyl esters, it is possible to get a high yield with this second ethyl group also, although in other cases it is best to stop the reaction when the first ethyl group has reacted, and to make use of the residual sodium ethyl sulphate, or ethyl hydrogen sulphate, for some other purpose.

COMMERCIAL ETHYL COMPOUNDS PREPARED

It is beyond the scope of this résumé to give complete directions for making all ethyl compounds, or even a list thereof, for it is realized that this work is still largely incomplete. It will be of interest, however, to mention some of the commercial products which have to date been successfully produced by means of ethylation with diethyl sulphate. Ethyl chloride, ethyl bromide and ethyl iodide have been prepared with great ease and in almost quantitative yields. The esters of the weaker inorganic acids, such as ethyl nitrite, ethyl sulphite, ethyl mercaptan and ethyl sulphide, are readily produced in highest purity and good yields. The esters of all organic acids attempted have been produced easily, and in such cases as ethyl cinnamate, where the value of the acid radical is relatively great, a highly pure derivative has been obtained with negligible loss of material. The ethyl esters of the higher fatty acids, such as ethyl laurate, ethyl oleate, ethyl stearate, etc., have been prepared easily, and through this means the pure fatty acids themselves have been readily isolated by redistillation of the esters. Ethylated phenols may be obtained quantitatively. Ethylated amino compounds are very easily prepared indeed, although care must be taken to get proper conditions to prevent the formation of complex mixtures of mono-, di- and tri-ethyl derivatives, as is common with all ethylations of amines. Finally, starch and even cellulose have been ethylated to give ethers,¹² in general similar to the esters of the

¹⁰CHEM. & MET. ENG., vol. 23, p. 833 (1920).

¹¹Ullman, *Ber.*, vol. 35, p. 322 (1902).

¹²Lilienfeld, Brit. Pats. 12,854 (1912) and 149,320 (1920); U. S. Pats. 1,217,027 (1917); 1,217,028 (1917). Clarke, U. S. Pat. 1,357,614 (1920). Worden, "Technology of Cellulose Esters," Van Nostrand, (1916), vol. 8, p. 2505.

same materials, but naturally more stable and less subject to hydrolysis and corrosion of metal in contact with the material thus produced.

The possible applications of this reagent in our future developments of chemistry are difficult to predict at this time; but, in view of the undeveloped possibilities which suggest themselves in the fields of dyestuffs, pharmaceuticals, solvents, plastics, varnishes and films, it would be safe to expect that the technical application of ethylene in the production of commercial diethyl sulphate will be of importance in the chemistry of the future.

SUMMARY

In brief, the advantages which this commercially new ethylating agent offers are:

1. It permits rapid and complete ethylation without pressure vessels or autoclaves.
2. It has a high intensity of reaction, thus economizing valuable material.
3. It avoids the necessity of recovering any expensive acid radical.
4. It may be handled and stored without loss due to its low volatility.
5. It is non-toxic, non-flammable and non-corrosive.

A Symposium on Industrial Management

VARIOUS phases of industrial management were discussed by well-known experts at the annual convention of the Industrial Relations Association of America, held in New York on Nov. 1-4. Secretary of Commerce Hoover, Secretary of Labor Davis, B. Seeborn Rowntree, president of the large British cocoa works of Rowntree & Co., Ltd., and many officials and employment managers for prominent American industries spoke on labor conditions, personnel work and such closely related subjects as departmental costs, living conditions, wages, seasonal production, and unemployment.

Space limitations prevent an extended account of the open meetings and sectional conferences, but a few papers of more intimate interest to our readers have been abstracted in the paragraphs which follow:

Human Relations in Industry.—A discussion of the fundamental principles of human relations in industry by L. A. Osborne, president of the Westinghouse International Electric Co., was well received by the convention. Mr. Osborne divided industrial relations into two categories, economical and ethical, and analyzed these according to his own viewpoint. He made a plea for cordial relations between employer and employee, saying that on no other basis could industry thrive. On the subject of wages he stated as his opinion that wages should be based on production.

Taking the Mystery Out of Business.—S. R. Rectanus, personnel director of the American Rolling Mills Co., explained how his company is winning the confidence of its employees by "taking the mystery out of business." Advisory committees are elected by secret ballot, the privilege of voting and holding office being confined to employees who have been with the company a year. These committees take up problems of production, working conditions and other matters which affect both the company and the workers. The objects of the company, the way in which it conducts its business, the conditions of the market in general and the eco-

nomics of business are discussed and made clear so that every man and woman in the plant has, or can have, a clear understanding as to the methods and practices of the company.

It is this company's belief that practically all of the mystery which has surrounded business so far as its employees are concerned is not only unnecessary but is a direct cause of much distrust and misunderstanding.

Use of Graphic Charts.—Along this same line, E. K. Hall, vice-president, American Telephone & Telegraph Co., stated that one of the principal causes of industrial unrest is the fact that working men and women feel that they have no standing in the industry, but are simply small cogs in a huge machine. One of the ways in which this misconception is being overcome is by the preparation of organization charts which include everyone in the central station or district, from the manager down to the janitor, making them all feel that they are part of the family. This is in distinct contrast to the usual organization chart which shows only the heads of various departments and leaves all the rest in an unclassified mass. The result of this change has been increased confidence and an excellent spirit of co-operation among the employees of the company.

Hoover's Analysis of Labor Unrest.—The third session of the convention was held in conjunction with a dinner meeting of the Academy of Political Science. Herbert Hoover, presiding officer, in pointing out the value of good will and co-operation in industry, gave a brief analysis of labor conditions as they exist today.

Mr. Hoover referred to the universal desire for the limitation of armament, not only internationally but industrially, stating that warfare is becoming more destructive year by year. He also referred to altercations between employer and employee, declaring that it was wholly idle to deny the existence of conflicting interests between these parties. "But," he added, "there are wide areas of activity in which their interests coincide. It is the part of statesmanship to recognize identity of interest where it exists in order to reduce the area of conflict."

Unemployment was given as largely responsible for industrial unrest. "One of the causes of ill will that weighs heavily upon the community," said the speaker, "is the whole problem of unemployment. I know of nothing that more filled the mind of the recent conference, while dealing mainly with emergency matters, than the necessity to develop further remedy, first, for the vast calamities of unemployment in the cyclic periods of depression, and, second, some assurance to the individual of reasonable economic security—to remove the fear of total family disaster in the loss of the job."

Viewpoint of the British Employer.—B. Seeborn Rowntree, president of Rowntree & Co., cocoa works, York, England, spoke on "Conditions Essential to Industrial Co-operation from a British Employer's Point of View." He complimented American business men upon the efficiency with which they have handled their material problems, but stated that the same effort is not being exerted on the human problems. Industrial unrest, according to Mr. Rowntree, is a reflection on the ability and intelligence of the employer. To secure industrial peace, he must pay the price, consisting of commensurate wages, sufficiently short hours, a guaranteed economic security to the worker, and possibly a proper share of the profits of the work.

Solid Solutions of Oxygen in Iron

TWO papers were read on this subject before the British Iron and Steel Institute's spring meeting, 1921, one by Dr. J. E. Stead and the other by J. H. Whiteley. In the former Dr. Stead notes that in general solid solutions in iron are electro-positive to pure iron, and therefore when in contact with the latter remain white on brief attack by a cupric reagent. However, many attempts to verify Le Chatelier and Bogitch's statement that iron and its oxide or oxygen formed such a solid solution were fruitless, even when electrolytic iron was burned on a magnesia-lined base in such a way that the fused iron was shot full of minute black globules and covered with thick layers of cinder. However, if strips of electrolytic iron or commercial soft steel were heated to 1,000 deg. C. in air, a thin sheath of finely crystalline iron (which resisted cupric attack) is found to separate the base and the adherent scale. White "resist" lines also appear at welded junctions.

More recently, Dr. Stead examined a steel casing very low in phosphorus from a hot blast stove, heated many years in an oxidizing atmosphere. It was extremely brittle; shock fracture commenced as intercrystalline at the surface, but deeper in was transgranular. Veins of oxide of iron completely separated the surface

He then investigated the effect of oxygen, phosphorus remaining constant. Very pure electrolytic iron was oxidized to scale in an electric muffle. This oxide was used to pack other pieces of iron into a small steel cylinder, the latter tightly plugged, cased in a strong silica tube and the whole heated 2 hours in a gas furnace to approximately 1,350 deg. C. On opening, the oxide had fused to a solid mass, and chemical analysis indicated that Fe_2O_3 had been partly reduced, as follows:

Unetched sections showed the metal to contain a number of new globular particles, thought to be of the same composition as the packing material. It is unknown whether this material worked itself in at high temperature, or separated from solid solution on cooling.

A pile consisting of several alternate layers of this oxidized and the original iron was prepared, placed in a tightly plugged steel cylinder containing nitrogen, heated and hammered down until the whole had welded together. Fig. 3 shows a cross-section of the weld after etching, which is not comparable with the least variation in phosphorus (Fig. 4).

Armco iron was then deoxidized by heating in H_2 for 2½ hours at about 1,350 deg. C., a pile of deoxidized and original strips made, and welded in a tube containing H_2 . Temperature was held below 900 deg. C., and

crystals, as shown in Fig. 1 (unetched), while white "resist" lines appeared after cupric etching (Fig. 2) at the surface, and on down, outlining the crystals, even below the point where oxide accumulations were formerly observable. This latter fact suggests that oxygen penetrates sound steel at the crystal boundaries, forming solid solutions, which, when supersaturated, produce insoluble oxide. Annealing in H_2 at 1,200 deg. C. removed the foreign material entirely at the grain borders, and with them the ability to form "resist" lines on cupric attack, either there or further down.

In view of the low P content (0.007 per cent), it was thought that phosphorus might have migrated to the scale, but chemical analysis failed to reveal any there. Instead S 0.80 per cent was found, evidently absorbed from the furnace gases. The globules within the iron crystals had the characteristic dove color of manganese sulphide—quite different from those at the grain boundaries—and indicates that this S may have been absorbed from the exterior.

Whiteley, in the second paper mentioned ("Cupric Etching Effects Produced by Phosphorus and Oxygen in Iron"), first shows that the cupric reagent clearly distinguishes phosphorus differences of no more than 0.018 per cent in oxygen-free electrolytic iron (Fig. 4).

welding was quickly done to prevent reduction of oxide in the original metal, and to avoid melting the $\text{FeO}:\text{FeS}$ eutectic present. After etching with picric acid, the reduced strips plainly have lost their oxide spots. The same, etched with Stead's reagent, is shown in Fig. 5. Here the deoxidized material is more resistant than the original, which gathered most of the copper. White resist lines appear at the junctions, but always in the original material. Crystallization can clearly be seen at high magnifications to take place across these resist lines, from piece to piece—a complete weld has formed, even though a heterogeneous solid solution remains. No such white resist lines occur after welding unoxidized electrolytic strips.

Apart from this effect, oxygen in uneven distribution has not been found by Whiteley to yield effects similar to those given by even the smallest variation of phosphorus.

Rubber Used During the First 6 Months of 1921

Data compiled by the Rubber Association of America show that during the first 6 months of this year 131,979,361 lb. of crude rubber was used in the manufacture of rubber products, and that 33,527,306 lb. was reclaimed from 45,669,424 lb. scrap rubber.

Structure and Properties of Alternately Electrodeposited Metals*

If Relatively Thin Layers of Nickel Are Interposed During the Deposition of Copper, the Growth of the Copper Crystals Is Restrained, and the Tensile Strength of the Deposit Is Increased—Applications of the Process

By WILLIAM BLUM
Chemist, Bureau of Standards

A FEW years ago attempts were made by the U. S. Bureau of Engraving and Printing to reproduce its printing plates by electrodeposition. It was then found that plates 0.25-in. thick, consisting entirely of electrodeposited copper (with nickel printing face) did not possess sufficient strength—i.e., they bent when in service upon the presses. George U. Rose, Jr., chief of the Engraving Division, who was conducting these experiments, conceived the idea of “re-enforcing” the copper plates by the deposition of layers of nickel at intervals through the copper. He then found that plates so produced possessed the necessary strength to meet the requirements. This process of depositing alternate layers of nickel and copper, which has been patented by Mr. Rose, is employed in the new electrolytic plant of the Bureau of Engraving and Printing.¹

PRINCIPLES INVOLVED

The purpose of this paper is to show that in so apparently trivial an innovation as the alternate deposition of two metals a new principle possibly of wide application is involved. Consideration by the author of the effect of the layers of nickel led to the thought that this is probably due not so much to the higher tensile strength of the nickel as to the influence of the nickel layers upon the structure and properties of the intervening copper. A few simple experiments and photographs showed that such is the case.

It has long been recognized that in the deposition of a metal the initial deposit is usually fine grained but that the crystals become larger as the deposit increases in thickness. This was well illustrated in the photographs showing the structure of electrotyping copper.² If, as may generally be assumed, fine-grained deposits have the greatest hardness and tensile strength, conditions leading to the formation of fine crystals are usually desirable, especially high current density, low temperature and agitation. For the thickness used in regular electrotyping—i.e., up to 0.25 mm. (0.010 in.)—there is no difficulty in obtaining relatively hard copper deposits by the application of these principles. When, however, as in the case in question, a thickness of 6 mm. (0.25 in.) or more is required, the use of a high current density leads to the excessive formation of “trees.” Moreover, with large plates the degree of agitation is practically confined to that obtainable by compressed air, and usually it is not feasible to apply artificial cooling to the solution. In consequence most of the thick cop-

per plates produced electrolytically in various plants have been deposited at low current densities and have had relatively low hardness and tensile strength.

EXPERIMENTS

If the effect of each layer of nickel is due to its influence in preventing further growth of the copper crystals, the actual change in mechanical properties—e.g., tensile strength—should be determined not so much by the relative thickness of the nickel and copper layers as by the frequency with which the nickel layers are interdeposited. In order to determine whether such is the case, a number of plates were prepared in which both the frequency and the thickness of the nickel layers were varied. For purposes of comparison a number of plates of pure copper were deposited. The plates were machined and ground to a smooth surface, after which specimens were cut and tested for tensile strength and elongation.³ The test results are shown in Table I.

On all these specimens an initial coat of nickel (about 0.025 mm. or 0.001 in.) was deposited. All the nickel layers were produced without agitation at a current density of 2 amp. per sq.dm. (19 amp. per sq.ft.) in “Watts’ solution” containing

	G. per Liter	Oz. per Gal.
NiSO ₄ ·7H ₂ O.....	240	32
NiCl ₂ ·6H ₂ O.....	15	2
H ₃ BO ₃	30	4

(from which as determined in subsequent experiments, relatively soft nickel is obtained). The copper deposits were made in an agitated solution containing:

	G. per Liter	Oz. per Gal.
CuSO ₄ ·5H ₂ O.....	200	27
H ₂ SO ₄	100	13

From the data in Table I it is evident that of those deposits which contained copper and nickel in the ratio of 10 to 1 (by thickness) by far the greatest strength was produced when the nickel layers were introduced most frequently. On the other hand the presence of twice the above proportion of nickel produced only a slightly increased strength. It is interesting to note the beneficial effect of increasing current density upon the strength and structure of the pure copper deposits, as has been pointed out by Bancroft⁴ and recently illustrated by the author.⁵ Thus in Fig. 1, it may be observed that as the current density is increased the long crystals in A are broken up appreciably at the higher current density used in B; which finally leads to the

formation of twinned crystals at still higher current densities. However, even at 6 amp. per sq.dm. (56 amp. per sq.ft.) marked treeing occurred, which was still more pronounced at higher current densities.

That the changes in strength produced by the nickel layers were caused principally by a decrease in the average size of the copper crystals is illustrated by the photographs of Fig. 2. In each case it may be observed that the copper crystals increase in size as de-

position continues, but that when a layer of nickel is interposed, further growth ceases and new fine crystals are deposited. Also it is obvious that in Fig. 2, B, in which the nickel layers are most frequent, the average size of the copper crystals is smaller than in A or C. It is true, however, that the copper crystals become slightly coarser in each layer as the deposition continues, which explains why the nickel layers do not entirely eliminate the roughness of the deposits. No

FIG. 2. STRUCTURE OF ALTERNATE DEPOSITS OF COPPER AND NICKEL ($\times 100$)

Thickness Ratio Cu:Ni	Layers of Each per Inch	Ultimate Tensile Strength
A — 10:1	90	32,000 lb. per sq.in.
B — 10:1	360	41,000 lb. per sq.in.
C — 5:1	170	42,000 lb. per sq.in.

attempt was made in these experiments to determine the extreme effects which might be produced by very frequent alternation as, for example, in a mechanically operated continuous process.

In addition to increasing the strength of the deposits, the presence of the nickel layers reduces materially the tendency to treeing. This is to be expected, as in effect a "tree" is simply a large crystal or series of crystals caused by favorable conditions. Among these is the high potential drop through the solution, which, under otherwise similar conditions, must accompany a high current density. Any procedure which will decrease the formation of trees is very helpful in permitting the use of higher current densities in the production of thick deposits.

That the above effects of alternation are not confined to these two metals is shown by Fig. 3, in which layers of silver (from the usual cyanide solution) are alternated with layers of copper from the sulphate solution. The choice of the two metals is limited only by the condition that, in the solutions employed, neither must cause deposition of the other by immersion to such an extent as to prevent proper adhesion of successive layers. (Where there is only a slight tendency for such deposition, it can be prevented by having the cathode connected in the circuit before introducing it into the solution.)

If the process depends upon the different structure of the interdeposited metal, the same result should be accomplished if both layers are composed of the same metal, provided they have different crystalline structures. It is well known that copper deposited from a cyanide solution is much finer grained than that from sulphate solutions. Accordingly in one experiment layers of copper from a cyanide solution were interdeposited between the layers from the sulphate solution. As seen in Fig. 4, the structure of the "sulphate copper" deposits is affected in just the same way, but not to so marked a degree, by the layers of "cyanide copper" as by nickel. No tensile strength tests were made on this deposit, but there is no reason to doubt that the change in structure was accompanied by an increase in strength.

APPLICATIONS

The possible applications of this process may extend to many operations in which the presence of another metal or of layers of the same metal is not objection-

FIG. 3. STRUCTURE OF ALTERNATE DEPOSITS OF COPPER AND SILVER ($\times 500$)

FIG. 4. STRUCTURE OF ALTERNATE DEPOSITS OF COPPER FROM SULPHATE AND CYANIDE SOLUTIONS ($\times 500$)

able. Copper is especially adapted to galvanoplastic operations, such as electrotyping, the reproduction of engraved plates, the manufacture of phonograph records, and of tubes and other irregularly shaped articles. In all of these processes the introduction of nickel layers may be found advantageous, in producing greater strength, and permitting the use of higher current densities, and possibly of thinner deposits.

Of even greater interest than the immediate industrial application of this principle is its possible bearing upon other problems in electrodeposition. If macroscopic layers of one metal produce such a decided effect upon the structure of the layers of another metal, it is entirely reasonable to expect that if the layers were much thinner, and ultimately molecular, still more marked effects would be produced. In other words, we would expect an electrodeposited alloy to have a much finer crystalline structure than either of its constituents deposited under similar conditions. This has been recently found by the author and his associates to be the case with lead-tin alloys.⁶

Similarly it is known that even small amounts of foreign metals in deposited metals, arising either from accidental impurities or from intentional additions to the bath, may exert profound effects upon the structure of electrodeposits. It appears reasonable to assume that at least part of their effect is due to hindering the normal crystal growth in the above described manner. Thus viewed, these observations are at least in general accord with the theory of the "wandering diaphragm moving boundaries" as proposed by Engelhardt,⁷ according to which the effect of colloids is caused by their migration to the cathode, accumulation upon points of (momentarily) highest current density and consequent retardation of crystal growth at those points. - The whole question presents a fascinating subject for investigation, and emphasizes the importance of a more extended study of the internal structure of electrodeposits.

The author is indebted to his associates, especially W. E. Bailey, H. E. Haring and L. D. Hammond, for assistance in the preparation and study of the plates described in this paper, and to H. S. Rawdon for the preparation of the photographs.

Recent Developments in the Sulphuric-Acid Industry—III*

A Survey of Novel Features in Design and Operation of Recently Developed Equipment for Nitration Process Plants, Including Acid Eggs, Mechanical Acid Pumps, Tank-Car and Storage Tank Unloading Devices, Acid Valves and Gas Fans

By ANDREW M. FAIRLIE
Consulting Chemical Engineer

IT IS the purpose of the present paper to discuss, in the light of recent advances, a few of the accessories of a modern nitration process acid plant, with especial attention to the types of acid eggs, pumps and valves, gas fans and acid coolers which have been developed in recent years.

Acid eggs have been for many years the established means of elevating acid to the tops of towers. The deficiencies of the eggs have long been recognized. The power cost is high; they require the constant attention of an operator, involving the expense, day and night, of pumper's wages; the eggs must be placed several feet below the supply tanks, which means the acid must be permitted to flow to a lower elevation than necessary otherwise; the acid must be delivered into a "splash-egg" above the top tanks, which means that all the acid pumped must be elevated higher than necessary otherwise; the supply line must have a check-valve, which is troublesome, or a hand valve, which is worse; the operation of the eggs is intermittent, involving fluctuations in the depth of acid in the top tanks, and fluctuations in the quantity fed into the towers per unit of time; there is much wastage of compressed air; and the violent escape of acid mist in the tower house damages tanks, floors and roofs.

Some improvement in these conditions was brought about by the appearance of the Bihn-Jones automatic air device, first marketed by the Schutte & Koerting Co., of Philadelphia, in July, 1915. By means of this device, shown in Figs. 17 and 18, the pumper could be eliminated part of the time, the wastage of compressed air was diminished, and the splashing at the top tank was reduced to almost *nil*. The valve is applicable to use with any flowing liquid, but its chief use, as developed, has been for circulating the acids over the towers in chamber-process sulphuric-acid plants.

Referring to Figs. 17 and 18, this air device is composed of:

First, a base (V), which contains a seat (L), to which a number of ports for the admission of compressed air lead from an air chamber, which completely surrounds the seat.

Second, a plunger (D) having a conical seat (E) on its lower surface, which contacts with the seat (L) in the base, thus completing the compressed air valve. There is also a flat circular exhaust valve seat (U) on the upper surface of this plunger.

Third, a hood which is bolted to the base, thus forming a cover for the apparatus, and a cylinder in which the plunger (D) moves. This hood contains an exhaust port, which connects with a vent pipe. Around the exhaust port of the hood there is formed a flat circular

seat (H), which contacts with the seat (U) on the upper surface of the plunger (D), and thus completes the exhaust air valve.

The operation of the device can best be understood by considering the arrangement shown in Fig. 19.

Liquid from a supply tank (A) flows by gravity through a check valve (C) into the blow-case (J) and rises until it reaches the base of the plunger (D), (Fig. 18) of the automatic air device (F), which it raises slightly, permitting compressed air to enter. The sudden release of the compressed air forces the plunger upward against its upper seat (U), thus closing the exhaust valve to the vent pipe (Fig. 17). The air thus prevented from escaping exerts its pressure on the top of the liquid, closes the check valve (C) and forces the liquid through the discharge pipe (G) to its destination. When the surface of the liquid falls below the

FIGS. 17 AND 18. BIHN-JONES AUTOMATIC AIR DEVICE

Fig. 17—Showing blow-case pumping. (Note raised position of plunger D.)

Fig. 18. Showing blow-case filling. (Note lowered position of plunger D.)

opening of the discharge pipe at the bottom of the blow-case, the compressed air follows the liquid out through the discharge line (completely clearing it of liquid), and escapes momentarily at the upper end of the line. The expansion of the air in the blow-case, due to the decreasing load as the liquid is forced out of the discharge line, causes a reduction in pressure in the blow-case sufficient to permit the plunger of the air device to drop into its lower seat by its own weight. This simultaneously closes the ports of the compressed air valve and opens the exhaust air valve, thus releasing the exhaust air in the blow-case. The check valve (C) now opens due to the head of the liquid in the tank (A) and the blow-case begins to fill, thus repeating the operation.

During the filling of the blow-case the exhaust air

*For Parts I and II see CHEM. & MET. ENG., vol. 25, Nos. 19 and 20, pp. 861 and 917, Nov. 9 and 16, 1921.

or gas which remains after pumping is displaced by the incoming liquid and escapes through surge-holes in the base of the air device, passes through openings at the side of the plunger and escapes through the exhaust port and the vent pipe (I) (Fig. 19). Fig. 17 shows plunger *D* in the raised position while the egg is pumping, and Fig. 18 shows plunger *D* in the lowered position while the egg is filling.

The manufacturers have recommended the use of

FIG. 19. AUTOMATIC VALVE MOUNTED ON ACID EGG AND CONNECTED TO ACID SUPPLY TANK

small eggs in combination with the Bihn-Jones equipment. However, it has been found in practice that the use of very small eggs with this device results in a very frequent up-and-down movement of the plunger, with resultant excessive wear on the seats. The result of this has been undue expense for mechanical repairs to the air device, which tends to offset to some extent its advantages. Where the egg is of reasonable capacity (4 tons 60 deg. acid or more) and the quantity of acid to be pumped is moderate, this device has proved to be a real asset. As the device, with its small air ports, reduces somewhat the normal speed of filling and discharging the egg, it may not be suitable for pumping very large tonnages of acid.

At the plants of the Tennessee Copper Co., where the quantity of circulating acid is exceptionally large, the supply and discharge lines for the eggs are of wrought iron, the former being 6-in. pipes, and the latter 4-in. At these plants the usual lead splash eggs at the top tanks have been replaced by cast-iron splash eggs, which have proved much more durable and less expensive to maintain.

On account of the deficiencies of the acid eggs, many attempts have been made to develop a satisfactory mechanical acid pump. These attempts have for the most part had negative results until recently. A number of acid pumps are now on the market, each with its peculiar claims to merit and each with its deficiencies. Four of these will be briefly described.

The Antisell pump, manufactured by the Chemical Pump & Valve Co., is of the packingless type, and the horizontal impeller, attached to a vertical shaft, is submerged in a body of acid at the bottom of a boot having a supply pipe directly connected to the supply tank.

Fig. 20 is a vertical section through one of these packingless pumps. This particular pump was designed to handle sulphuric acid against a head of 100 ft. with an efficiency of 45 per cent. The acid by gravity

enters the boot surrounding the vertical shaft and proceeds to the pump impeller through the annular opening in the pump cover. The acid itself thus forms a perfect seal against the admission of air and dispenses with the troublesome packing glands and packing of horizontal-shaft pumps.

Fig. 21 shows a type of lead packingless pump designed for handling solution containing 24 per cent sulphuric acid at the rate of 3,500 gal. per minute against a head of 40 ft., developing an efficiency, it is claimed, of 73 per cent. A distinct advantage of this make of pump is that any element of the pump may be taken apart for cleaning, repairs or renewal without disturbing the adjacent parts of the pump or disconnecting feed or discharge lines. The manufacturers state that the actual time required to change an impeller is less than 1 hour. The figure illustrates one of twenty pumps furnished the New Cornelia Copper Co., of which it is

FIGS. 20 AND 21. TWO VIEWS OF ANTISELL PACKINGLESS PUMPS

Fig. 20. Vertical section of pump.

Fig. 21. Special pump designed for handling dilute acid in large quantities.

stated that several have operated for 3 years without repairs. The acid pumped, however, was, as stated, weak and probably cold. In this pump the packing trouble inherent in all horizontal-shaft pumps has certainly been eliminated, the parts of the pump are easily accessible for replacement or repair, and the capacities claimed for the pump have been realized. Possible objections to the pump may be that the power efficiency is less than with the packed pumps, that the expense of installation, with massive concrete pillar, is excessive, and that the long overhang, without bearings at bottom of shaft to keep the revolving impeller in alignment, may result in undue vibration or excessive wear on the bearings and other parts of the pump.

The Ceco pump was first used in the chemical indus-

FIG. 22. CECO ACID PUMP WITH DIRECT-CONNECTED MOTOR

try in connection with the manufacture of phosphoric acid in the plant of the Victor Chemical Works, at Chicago Heights, Ill. On account of the corrosive nature of the phosphoric acid, together with the heavy scale which formed in pumps, valves, pipe lines and all other equipment in use for handling the crude acid, the conveying of this material was a difficult problem. After a thorough trial of the pump all other means of conveying phosphoric acid at this plant were abandoned, and it is said that this company has at the present time more than 100 of these pumps in use.

The first pump of this type was installed in 1914. The manufacturers (the Chemical Equipment Co., of Chicago, Ill.) state, however, that the pump was not perfected and put upon the market until 1918. The pump was patented under date of Oct. 19, 1920, and other patents are pending.

Ceco pumps are made of antimonial lead or of other alloys, according to the requirements, and are made in four standard sizes, with suction and discharge diameters respectively as follows:

Size	Suction Diameter, In.	Discharge Diameter, In.
A.....	1.5	1.0
B.....	2.0	1.5
C.....	2.5	2.0
D.....	3.0	2.5

The capacities of the several sizes depend of course upon the head against which the pumps are working.

FIG. 23. CECO ACID PUMP SHOWING SUCTION HEAD REMOVED

The pump can be arranged for either belt drive or for direct-connected motor as in Fig. 22.

While the Ceco pump is generally classified as a centrifugal pump, it might more properly be termed a displacement pump, inasmuch as there is no volute, and the liquid is merely forced out of a center compartment, or pressure chamber, into an annular space of uniform cross-section, or discharge chamber. These two chambers are clearly shown in Fig. 23, a photograph of a Ceco pump with suction head removed. The discharge of the pump proper is at the top of the discharge chamber, which slopes equally to each side of the pump, and is thus designed to eliminate pockets for the accumulation of gases and to render the pump proof against gas-binding. As long as there is sufficient liquid within the pump to seal the clearance on each side of the impeller, the pump is said to handle a mixture of liquid and gas without difficulty.

An interesting application of the Ceco pump has been made possible by the development of a special "priming system," patented under date of Sept. 2, 1919. By means of this priming system and without the use of

FIG. 24. DIAGRAM OF PRIMING SYSTEM FOR UNLOADING TANK CARS OR STORAGE TANKS

check valves or other moving parts, the pump with primer attached will withdraw acid through the dome of tank cars or storage tanks, thus dispensing with the need of bottom outlets. The greatest vertical distance that acid of 60 deg. Bé. can be lifted by means of the suction effect of the priming system is 16 ft. After entering the pump the acid can be elevated, by pump pressure, a vertical distance of 40 to 90 ft. more, according to the capacity of the pump used. Fig. 24 is a diagram of a priming system for unloading tank cars. Referring to this drawing, tank B is superposed above tank A, and these two tanks are called the priming tanks. A pipe connects the upper part of tank A with a tank car, and another pipe connects the lower part of tank A with the pump. The discharge of the pump is connected by a pipe with the bottom of tank B, and from the top of the latter another pipe conveys the acid to any place desired.

When this apparatus is first installed, tank A is

first filled with acid to the static level just below the discharge end of the suction pipe from the tank car. On this pipe a suction effect is produced by the act of starting the pump, caused by the emptying of the contents of tank A by gravity into the pump. This suction effect pulls the acid out of the tank car, through a pipe inserted through the dome, and the outflow of acid continues until the tank car is emptied. When this happens, air enters the pump and the pumping operation ceases. The pump is then stopped, and the acid flows from tank B through the pump into tank A, whereby the latter is automatically primed for unloading the next tank car.

Another use for the primer is in connection with the withdrawal of acid through the dome of deep storage tanks. Wherever the acid manufactured contains much sediment, which may be allowed to settle to the bottom of the storage tank and leave a body of clear supernatant acid, this device may prove useful in withdrawing the latter for shipment without disturbing the sediment at the bottom of the tank.

Acid pumps made of antimonial lead are open to the objections that the metal is relatively soft, is readily corroded by sulphuric acid and nitrous vitriol, and is subject to erosion by the particles of scale or other solids held in suspension by the acid, and thus the life of the lead pumps is comparatively brief. Duriron is well known to the chemical industry as a hard, brittle metal, much more resistant to the corrosive and erosive actions of acids than any of the lead alloys. Duriron acid pumps have been on the market for a number of years, but they have never come into general use for circulating acids over Gay-Lussac and Glover towers, due, no doubt, to the trouble experienced in keeping the stuffing box suitably packed.

In June, 1920, a Duriron acid pump of new design was placed on the market by the Duriron Co., Inc., of

FIG. 25. ASSEMBLY DRAWING OF DURIRON CENTRIFUGAL PUMP

1—Volute. 2—Suction elbow. 3—Runner. 4—Pump cover. 5—Packing gland.

Dayton, Ohio. The main features of this pump are: (1) Packing under slight vacuum while pump is in operation. (2) A helical impeller. (3) Accessibility of revolving parts without disturbing either suction or discharge line. (4) Rotatability of both volute and suction elbow to any position desired, in order to fit existing pipe lines.

Fig. 25 shows an assembly drawing of this new centrifugal pump, with 2-in. suction line and 1.5-in. discharge. In this pump it is claimed that the packing cannot be touched by the acid while the pump operates, inasmuch as the stuffing box is under a slight vacuum.

However, if the pump should be stopped without first closing a valve at the bottom of the discharge line, it is likely that here, as with all other horizontal-shaft pumps, some acid might enter the stuffing box and cause slight leakage. The pump is furnished for either direct-connected motor or for belt drive.

Fig. 26 shows the belt-driven type of pump. The capacity of this pump is stated to be 20 tons 60 deg. Bé. acid per hour at a head of 80 ft., with power consumption of less than 7 hp.

The speed of the pump can be regulated to deliver any quantity up to the maximum capacity. After removing the cover plate from that side of the pump opposite the stuffing box, the runner and shaft can be removed without disconnecting either the inlet or the outlet pipe. The shaft is of machine steel, and is covered by a Duriron shroud projecting through the

FIG. 26. DURIRON CENTRIFUGAL PUMP FOR BELT DRIVE

stuffing box. A web, cast between the top of the volute and the discharge flange, is designed to permit the escape of trapped air and prevent air-binding.

The Lewis centrifugal acid pump, like the Antisell pump, is a vertical packingless pump. The primary business of its manufacturers, the Charles S. Lewis Co., of St. Louis, Mo., was the manufacture of pumps for the circulation of cooling water or brine in refrigerating systems. The company's first pump for the elevation of acid was built in the early part of 1913. It was designed for pumping 60 deg. acid from the base of a Glover tower to the tank on top of a Gay-Lussac tower, and all parts were of cast iron except the shaft and casing bolts, which were of steel and wrought iron, respectively. This pump, of the vertical submerged type, was driven by a direct-connected motor. Fig. 27 is a photograph of this unit. This pump had 2-in. pipe connections, and, driven by a 4-hp. vertical motor, was good for a head of 70 ft. when pumping 60 deg. acid. It is now obsolete.

The principal features aimed at in designing this pump are listed below in the order of their importance: (1) Elimination of stuffing boxes and packing. (2) Production of a self-contained unit capable of being completely assembled in perfect alignment before installing at the acid plant. (3) Reliability and durability. (4) High power-efficiency. The first of these conditions was wholly satisfied by this first submerged pump. The acid entered the pump at the center on the upper side and was discharged below at the side. The second condition was also satisfactorily met. The pump was assembled and connected to the motor by means of the cast-iron frame which tied the pump to the main plate supporting the motor. The fourth condition was also complied with by this pump (which was a two-

stage machine), inasmuch as the power efficiency, with the pump delivering 10 tons per hour against a head of 70 ft. with power consumption of about 2.5 hp., was computed to be 45 per cent.

The third condition—reliability and durability—was the only one which this first pump did not fully satisfy. The pump discharged more acid than was being fed to its supply tank, with the result that it pumped all the acid out of the lower tank and drew considerable air into the impeller. Then the pump was shut down to install a throttle valve, and the next day, on attempting to start it, the impeller was found to be firmly cemented to the stationary parts of the pump. In trying to loosen the impeller, several of the small internal parts were broken and had to be replaced, and the pump then operated satisfactorily. Further experience showed that the pump could be stopped and permitted to stand for some time, without its sticking, provided it was kept submerged and free from any admission of air. It was assumed that the film of acid adhering to exposed parts of the pump absorbed from the air some moisture which diluted that acid to a strength capable of corroding the iron parts to which it adhered, and that a sulphate of iron formed, which caused the troublesome cementing of the moving parts to the fixed parts. By carefully excluding air and by keeping the acid up to 60 deg. strength, very reliable service was obtained, and it is said that this pump would do continuous duty 24 hours a day for eight or nine months before it was necessary to change the impeller or repair internal parts.

The development of the Lewis pump of today has proceeded from this original design. By placing a sub-

The new design was a single-stage pump, and it was found that the additional power required to operate it on the same duty as the former two-stage submerged pump was more than compensated for by simplicity of assembling and repairing. Fig. 28 shows the present type of Lewis centrifugal pump with 5-hp. direct-connected motor, embodying these improvements.

No attempt was made by the Lewis company to handle acid weaker than 60 deg. Bé. until 1916, when it built its first hard lead pump. The main difficulty to be overcome was to find suitable material for guide-bearings at the lower end of the shaft, which the

FIG. 29. PERFORMANCE CURVES FOR LEWIS PUMP HANDLING 60 DEG. ACID

company considered desirable, to hold the shaft and impeller true and free from vibrations. The problem was finally solved by Duriron bearing bushings in the lead pump casing, and by covering the shaft, at the parts revolving within these bushings, by Duriron sleeves. These Duriron bushings and sleeves were ground and polished to obtain adequate bearing surfaces. The lubrication afforded by the acid pumped was found to be sufficient.

Other obstacles, such as unsound lead castings and coarse-grained Duriron, were gradually eliminated, and the manufacturers now state that indications point to a life for the hard lead casings of this pump, when operating on weak sulphuric acid or nitrous vitriol, of three or four years. The wearing surfaces in the pump, however, do not last that long, their life being from six months to two years, depending on the amount of grit or sediment in the acid pumped. These wearing surfaces can be renewed at small proportional cost without renewing the casing. Practically no change has been made in the design of the hard lead pump during the past four years. The improvements have been confined to the quality of the materials entering into the parts of the pump.

In Fig. 29 are given performance curves showing capacity and head at various speeds, also brake horsepower. The curve shows that the pump will deliver 400 tons per day against a 62-ft. head equal to 46 lb. pressure when operating at a speed of 1,720 r.p.m. The horsepower required is 3.8.

The outstanding feature distinguishing this pump from the Antisell pump lies in the centering of the lower part of the shaft in fixed guide bearings. This very feature, while it keeps the shaft always in perfect alignment, exposes the pump to the criticism that these guide bearings have to be frequently renewed. The internal parts are rather inaccessible. To get at them the pump has to be completely dismantled and turned

FIGS. 27 AND 28. LEWIS ACID PUMPS

Fig. 27. Vertical submerged type (now obsolete).

Fig. 28. Modern type vertical acid pump for direct-connected motor.

stantial cast-iron boot around the acid inlet to the pump, the submerged pump has been converted into an outside vertical pump without losing any of the advantages of the submerged type and with the advantage gained that only the internal surfaces of the pump are exposed to acid, all bolts and nuts being kept on the outside, free from acid corrosion.

over on its side. The maintenance cost of these pumps, given by the manufacturers as about \$24 per month per pump, is high as compared with the maintenance cost of acid eggs. The net saving, however, due to lower pumping costs for power and operating labor, is said to more than compensate for the higher repair costs.

A number of new acid valves have been developed since 1914, and among these three important types will be discussed.

As was the case with the Ceco pump, the Ceco valve

FIG. 30. CECO ACID VALVE ARRANGED FOR STRAIGHT-WAY CONNECTION

was developed at the plant of the Victor Chemical Works, Chicago Heights, Ill., because of the difficulty experienced by this company in finding on the market a valve suitable for contact with crude phosphoric acid. In designing this valve, the features aimed at were: (1) A removable seat which could be withdrawn without disconnecting the entire valve and which could not corrode in place. (2)

(3) A seat which would not accumulate scale. (4) Flexibility as to angle of installation. (5) Operating mechanism inaccessible to acid or acid fumes. (6) A packing gland without studs.

Fig. 30 is a photograph of a 3-in. valve of this type, and it is seen to be of peculiar design. The removable seat is made of a flat slab of metal held in place between two flanged faces on the valve body. The seat is identical as to shape on both sides, thus making it reversible, and it can be removed without disconnecting the valve from the line. Only a few minutes are required to reverse or replace a seat.

FIG. 31. SECTION AND PLAN OF PACKINGLESS VALVE

In the ordinary valve, a tapered plug fits into a tapered seat, and any accumulation of scale or sediment on either plug or seat prevents effective closing of the valve. In the Ceco valve, the hole within the slab seat is cylindrical, and on a new valve the seating edge is quite sharp. Even after a valve has seen considerable service, the manufacturers claim, the seating is virtually a line contact. This means a minimum of area for the deposit of scale or sediment, and if scale does form on either of the seating members, it is said that the act of closing the valve tends to break away the scale. To prevent sticking of the plug, a relieving taper is provided thereon. A taper is machined also on the upper side of the plug, and at the top of the valve body another seat is machined, so that when the valve is wide open, the upper part of the plug is again seated on a line contact, the object being to seal the stuffing box against leakage, and permit the repacking of the valve while under pressure.

In order to broaden the scope of application of this valve to service, the body of the valve is divided into two parts at an angle of 45 deg. This permits of assembling any valve in either a straight or an angle position. Thus, using the same valve parts, the straight-way valve shown in the figure can be changed into a right-angle valve by turning that part which is on the left of the removable seat 180 deg., so that the valve stem and handle are below the left-hand flange, instead of above it.

FIG. 32. SECTION OF DURIRON GATE VALVE

Fig. 31 is a section and plan of a float valve of the packingless type manufactured by the Chemical Pump & Valve Co. The valve is provided with a flexible diaphragm which walls off the acid from the bearing of the valve stem. There is consequently no need of a stuffing box or packing. The flexible diaphragm is of lead, if the valve is to be used with sulphuric acid. The manufacturers state that owing to the limited movement of the diaphragm, the valve may be opened many hundreds of times before the lead cracks. When the lead does crack, it becomes necessary to drain the line, open the valve and put in a new diaphragm. It should be noted that owing to the design of the valve, the line cannot be drained unless the valve, when installed, is placed on its side. This valve is made in all sizes from 1 in. to 18 in., the capacity of the latter being 5,000 gal. per minute.

Fig. 32 shows a section of a Duriron gate valve which was first put on the market in June, 1920. It is a valve of the rising stem type. As the metal is highly resistant to corrosion, it is claimed that this valve will not stick under the most trying conditions. Gate valves of the ordinary type are inefficient as a positive shut-off for acid, particularly if the acid handled contains solids in suspension. This valve has double-hinged disks which

the manufacturers claim afford positive closure on both seats, and the valve can be used against pressure from either direction. The wedge action of the stem eliminates any wear on disks or seats, and the valve is so positive in its action that it is said to be useful with gases as well as with liquids. The valve can be packed while under pressure.

LARGE GAS FANS

The construction during the war of acid-making units of large capacity led to a demand for larger gas fans. This demand was recognized by the Pratt Engineering & Machine Co., of Atlanta, Ga., which in 1918 developed a fan which has a rated capacity of 15,700 cu.ft. of free air per minute against a pressure of 1.75 in. water gage, at a speed of 450 r.p.m. This compares with a rated capacity for the company's next largest fan of 10,000 cu.ft. per minute against the same pressure, at a speed of 560 r.p.m. The large acid plant built for the Government at Little Rock, Ark., was equipped with the larger Pratt fans. A large capacity acid-gas fan is also manufactured by the Buffalo Forge Co., Buffalo, N. Y., and has been on the market for some time. The Schutte & Koerting Co., Philadelphia, has designed some improvements to its acid-gas fan, and the new model was first marketed in 1916. The features distinctive of the new type are: (1) A blast wheel webbed so as to close entirely the spaces between blades at the side opposite the gas intake, the webbing being continuous from tip of blade to hub. (2) A blast wheel housing, cone-shaped at the side opposite the gas intake, so as to conform to the shape of the webbing between fan blades, and with smallest practicable clearance between webbing and cone-shaped part of housing, from tip of blades to hub.

This new model, like the Pratt and Buffalo fans and like most other fans designed for use beyond the Glover tower, is made of antimonial lead. On account of the low tensile strength and relatively low resistivity to corrosion by acid gases of this alloy, the need has long been felt for a material, applicable for use in the blast wheels and housings of acid plant gas blowers, which would be more durable in service. The Duriron Co., of Dayton, Ohio, has endeavored to supply this need with a Duriron fan, first marketed in January, 1920. It is made as yet in small sizes only, from 3 in. to 12 in. The 12-in. fan is said to be able to handle all the gas produced by burning 17 tons of sulphur in 24 hours, and can be operated safely at a speed of 1,800 r.p.m.

The impeller wheel will withstand erosion as well as corrosion, and the manufacturers recommend it for handling gases containing solid particles in suspension. Wherever this fan is used, the brittleness of the metal must never be overlooked, in tightening bolts or in moving the runner or the cap. One moment's carelessness in handling Duriron shapes has often caused the instant destruction of an expensive casting.

CAPACITY OF GAS FANS

Considerable uncertainty is found among sulphuric-acid manufacturers regarding the actual capacity of the various types of acid-gas blowers for moving gases. The capacity figures quoted by the blower manufacturers are received with a great deal of skepticism. It appears that the matter of determining the true capacities of the blowers for moving acid gases at the temperatures of such gases in an operating plant, and making due deductions for such items as air leakage at the shaft, steam coming over from the Glover tower with the gas,

etc., has not been attacked by the blower manufacturers in the scientific and convincing way which the problem deserves. To determine the capacity of a blower for delivering free air is a difficult problem in itself. To determine the capacity of a blower for moving hot moist acid gases is more difficult still. The problem should not, however, be neglected, and the sooner the blower manufacturers begin to determine scientifically the real acid-gas-moving capacities of their machines the sooner may the industry expect improvement in their efficiency.

IMPROVEMENTS IN ACID COOLERS

No recent developments of merit in acid coolers have appeared. The large rectangular acid coolers of the Calumet & Arizona Mining Co., described and illustrated by Wells and Fogg,¹⁸ while they conserve ground space and accommodate a very large linear length of lead pipe which affords a high area of external cooling surface, are not regarded as efficient coolers. In order to avoid regions of stagnant acid within a cooler of such large dimensions (capable of containing 5,000 linear ft., or nearly one mile, of 1½-in. coiled lead pipe), numerous baffle walls, dividing the cooling tank into numerous small compartments, and alternate top and bottom acid outlets between adjacent compartments, are needed, thus forcing the whole volume of acid, in its progress through the cooler, to take an alternate up and down movement along the vertical length of each coil, and come into direct contact with a maximum area of water-cooled lead pipes. The manner of connecting the coils to obtain a counter-current flow of water to acid needs special study.

Atlanta, Ga.

(Part IV will appear in a subsequent issue.)

Imports of Iron and Steel From Europe

Up to the end of August United States imports of iron and steel from Europe this year have aggregated 17,104 tons. More than 60 per cent of the total has been pig iron and semi-finished steel, with bars and sheet and plates making up the bulk of the remainder. Belgium alone sent nearly 60 per cent of the imports.

The following table shows in detail how the different products imported were divided among the various countries of origin.

IMPORTS OF IRON AND STEEL FROM EUROPE, EIGHT MONTHS OF 1921

Articles	All Europe, Tons	Belgium, Tons	Sweden, Tons	United Kingdom, Tons	Germany, Tons	Czechoslovakia, Tons	France, Tons	Other, Tons
Pig iron.....	7,896	7,191	130	400	125	...	50	..
Billets.....	2,736	2,422	265	...	48	...	..	..
Steel bars.....	2,685	348	1,171	588	141	344	35	58
Sheets and plates.	1,867	100	113	1,367	281	3	3	..
Iron bars.....	1,103	128	910	53	3	9	..	..
Wire rods.....	502		466	26	1	6	1	2
Tin plate.....	276			276	..	...	..	..
Structural steel...	39			8	31	...	..	..
Total.....	17,104	10,189	3,055	2,718	630	362	89	61

Belgium has been the chief factor in supplying pig iron and billets, but other lines from Belgium have been relatively unimportant. Sweden has been strongest in imports of bars and wire rods, and the fact that Sweden stands next to Belgium in total tonnage has not generally been recognized by current reports regarding competition of European steel in domestic markets.

Pulverized Coal in the Iron and Steel Industry

BY F. P. COFFIN
General Electric Co.

THE principal application of pulverized coal in the iron and steel industry are for the following classes of furnaces:

Heating furnaces:

Heating, reheating and forging.

Continuous heating, for blooms and billets.

Annealing malleable iron and steel castings and plates.

Sheet and pair (steel bars are heated for rolling into pieces).

Busheling and puddling (malleable iron).

Tin pots.

Galvanizing pots.

Melting furnaces:

Open-hearth steel.

Malleable iron.

For rough work the fuel is often burned in the same compartment with the work. For more finished work, where ash and slag may have a deleterious effect, a separate combustion chamber is frequently provided, and the two compartments are separated by a low bridge-wall. A large part of the ash collects in the bottom of the combustion chamber while the flame plays over the bridge-wall, and is long enough to extend over the work and to heat it by direct radiation. When substituted for natural gas, increased thermal efficiencies have been attained owing to the greater proportion of radiant heat emitted by the flame.

TYPES OF FURNACES

In small forging furnaces the coal and air are sometimes introduced through opposed tuyeres in order to avoid the impingement of the flame on the wall opposite the burner. A typical small forging furnace is shown in Fig. 1. This is equipped with opposed tuyeres and the secondary or volume air is divided between the two, while the coal is fed into one side only, being carried by the primary air which forms a small proportion of the air required for combustion. When warming a cold furnace, a hot spot is visible where the blasts impinge. As the brickwork becomes heated, this spot fades to a uniform glow which fills the whole interior. It is claimed that the introduction of all the coal on one side gives the best results. This furnace is located in the drop forge shop of the American Locomotive Co., in Schenectady, N. Y.

One of the most modern installations for burning pulverized coal in a sheet-rolling mill is to be found in the plant of the Newport Rolling Mill Co., at Newport, Ky.¹ Natural gas was formerly used as fuel.

The output, when burning pulverized coal, so greatly exceeded expectations that it was only necessary to re-equip six furnaces to handle the same output as eight stoker-fired annealing furnaces of the same size.

The following figures have been submitted as average production data attained at the plant: On the slab-heating furnaces, maximum fuel consumption of 180 lb. of coal per ton of product, though it is stated that considerably less than this amount per ton may be

taken as the average run. On the sheet and pair furnaces, fuel consumption covering long periods has not exceeded 275 lb. of powdered coal per ton of sheets produced. On the annealing furnaces, fuel consumption using powdered coal is reported well under 170 lb. of coal per ton of sheets annealed. On the galvanizing pots, fuel consumption below 110 lb. per ton, on the average, and considerably less than this average for favorable weight sheets.

Furnaces for melting and refining steel by the basic open-hearth process are fired with pulverized coal in a number of plants. A furnace of this type is shown in Fig. 2, equipped for firing with pulverized coal by the Bonnot system. The practice is to fire the fuel from both sides of the furnace on the reversing principle with a high velocity blast. In some installations the air required for combustion is delivered to the burner at a pressure of 1 lb. per sq.in. by a centrifugal compressor, in others by a fan blower at 8-oz. pressure.

According to N. C. Harrison² of the Atlantic Steel Co., Atlanta, Ga., "the hearth of a pulverized coal open-hearth furnace is practically the same as the hearth of any other open-hearth furnace; the uptakes, slag pockets and checker chambers, however, are entirely different. The uptakes are made as small as possible so as to hold the gases in the furnace as long as possible without blowing, and the slag pockets are made as large as possible so that the gases will have a slow velocity going through them, thereby depositing a large percentage of the heavy particles that are in the outgoing gases. On account of this heavy deposit, removable slag pockets, or very deep stationary pockets, should be used to collect this accumulation. Where removable slag pockets are used, they are taken out and cleaned and replaced about every two weeks. Only one checker chamber is needed on each end of the furnace. If the checker chamber is large enough, these chambers should be built up with large tiles and laid in such a manner as to form vertical flues, having openings of at least 6 x 9 in., or, better, 9 x 11 in. In some cases no checkers are

²Consult "Pulverized Coal as a Fuel," *Mechanical Engineering*, August, 1919.

FIG. 1. VIEW OF A SMALL FORGING FURNACE WITH PULVERIZED COAL BURNER

Excerpt (by permission) from material prepared for Bacon and Hamor's "American Fuels," now in press of McGraw-Hill Book Co.

¹Consult "Burning Pulverized Coal in a Sheet Mill," *Iron Age*, Dec. 11, 1919. "Burning Powdered Coal in a Rolling Mill," by H. T. Matthew, *Combustion*, April, 1920.

used at all, but the chambers are filled with baffle walls with openings from the outside so that the accumulation between these baffle walls can be raked out. All passages from slag pockets to stack must be as straight as possible and, wherever bends must be made, some agitating device should be installed. The reversing valves are usually of the mushroom and damper slide type.

"The best coal for use in pulverized form in open-hearth practice is a bituminous coal as high in volatile matter as possible, and preferably low in ash. It should never contain below 32 per cent of volatile nor more than 8 per cent of ash. It is necessary that the coal be as finely ground as possible so that about 97 per cent will pass through the 100-mesh sieve; preferably 90 to 93 per cent, and not less than 85 per cent through the 200-mesh sieve, and from 70 to 75 per cent through the 300-mesh sieve. This is necessary for quick combustion and for the elimination of sulphur. By this very fine pulverization we attempt to have complete combustion before the flame strikes the bath, thereby burning out the sulphur in the coal to SO_2 gas, which passes up the stack. Some 6 or 8 ft. is necessary from the end of the burners to the bath.

"The advantages and disadvantages from the use of pulverized coal, as compared with hot producer gas, as

alterations we expect to get much longer life out of the checkers, and, consequently, longer runs out of the furnace. As a result of this continued development, we believe that inside of six months we will obtain a 25 per cent increase in production over the gas producer furnaces of the same size.

"Sulphur does not give any trouble as long as there is a good draft and the furnace is working hot. We are now using coal with over 1 per cent of sulphur and getting good results. If checkers get clogged up and the furnace begins to blow, due to lack of draft, we have trouble with the bath taking up sulphur. The furnace is under complete control of the first helper, as to amount of coal being used, as well as the air blast and temperature. The flame, using the same coal as on gas producer, is hotter, which allows us to use a greater percentage of scrap per ton of steel, thus reducing the consumption of high-priced pig iron; also it enables us to obtain a greater number of heats per week.

"The finished steel is quieter in the molds, due to not being overoxidized, as the coal coming directly in contact with the bath has a greater reducing action. We feel reasonably certain that the oxidation losses are less with pulverized coal than with producer gas. All gas house troubles are eliminated (clearing fires, burning-out

FIG. 2. TYPICAL OPEN-HEARTH FURNACE WITH PULVERIZED COAL BURNER

a fuel for open-hearth furnaces, from observation of its use up to date are as follows:

"All the heat is generated in the furnace, while in the case of the gas producer, from 18 to 25 per cent of the heat units are lost in the producer itself when converting the coal into gas. The higher flame temperature results in a greater number of heats per week. Open-hearth furnaces using powdered fuel operated on a very low fuel consumption fully equal to the best producer gas practice, and much better than the average of the older plants in this country; at the Atlanta plant the coal consumption is about one-third less than with producer gas. Coal can be pulverized in plants of about 100 tons daily capacity and delivered to the furnace for approximately 50c. per ton, which is about the same as the costs for gasifying coal in gas producers.

"The use of this fuel in metallurgical furnaces has been developed to only about 75 per cent of its ultimate value. In our plant this open-hearth furnace has been shut down oftener than the producer gas furnaces of the same size, due to checkers and slag pockets filling up with cinders and slag after about 80 heats. We believe, however, that we are gradually overcoming these troubles by decreasing the size of the uptakes and enlarging the slag pockets as mentioned above. Now, only the fine particles are going to the checkers and are being blown off daily by compressed air. By these

flues, etc.), although the pulverizing plant must be given attention as to dryness and fineness. Refractory costs have been greater on the furnace using pulverized coal than on gas producer furnaces. I believe, however, that our steadily increasing familiarity with the use of this fuel will enable us to reduce this item nearly to the corresponding cost in producer gas furnaces."

The pioneer installation for firing basic open-hearth steel furnaces was made by the National Malleable Castings Co., at Sharon, Pa., about 1914, and has been operated successfully since that time. Pulverized coal has displaced fuel oil without any sacrifice of tonnage or quality of the product and with gratifying results.³

In some recent open-hearth furnace installations, built from designs made by the Quigley Furnace Specialties Co., vertical baffle walls have been used in the regenerative chambers in place of checkers.

A number of basic open-hearth installations have been made at plants of the United States Steel Corporation. Pulverized coal has been applied to the acid open-hearth process, but has not been found suitable.

Pulverized coal has been used in a number of malleable iron foundries for annealing castings, some of the installations dating from the earlier period when more

³Consult also "Pulverized Coal Systems in America," by L. C. Harvey, Fuel Research Board Special Report No. 1, London, 1919. Also "Pulverized Fuel, Its Use and Possibilities," by W. J. Dick, Commission of Conservation of Canada, Ottawa, 1919.

coarsely powdered coal was used. Until recently, however, it had not been successfully used for melting purposes.

What is probably the pioneer installation for melting malleable iron⁴ was made in 1919 at the malleable foundry of the General Electric Co., at Erie Pa. (Fig. 3.) This is an air melting furnace with a capacity of 10 or 15 tons and is equipped with a 22-in. burner. Considerable experimenting was necessary at first to obtain the most satisfactory arrangement and the furnace has recently been greatly simplified by discarding three features which were considered necessary at the start.

The first was a water-cooled damper, at the back bridge wall, which was thought necessary for controlling the stack draft. The second was a combustion chamber between the burner and the furnace. This was thought necessary to obtain complete combustion of the coal. The third was a top blast which was installed because it was used in all malleable iron foundries.

successful operation by the Combustion Economy Corporation, with pulverized coal as fuel in one of the largest malleable iron foundries in the United States. This furnace was of 10-ton capacity and was formerly fired by hand. Only a few slight changes were necessary in the firebox, such as filling the ash pit, lowering the front bridge wall, removing the top blast and altering the firebox front to provide for the burner pipe.

The general dimensions of the furnace are as follows: Length between bridge wall 15 ft. 6 in., width at tap-holes 5 ft. 6 in., firebox 40 x 59 in.; diameter of stack 29 in., height of walls at tap holes 31 in., depth of metal at tap holes 9 in. This is considered a very small furnace. On larger furnaces the results should be even more favorable.

The method of introducing the burner into the furnace is illustrated in Fig. 3.

A comparison of the operation of this furnace with hand-firing and with powdered coal is as follows:

FIG. 3. VIEW OF A 15-TON AIR-MELTING FURNACE FOR MALLEABLE IRON WITH PULVERIZED COAL BURNER

The company's engineer, however, considered this custom to be the result of superstition rather than necessity and the top blast was finally discarded. These sweeping changes have added greatly to the efficiency and simplicity of operation of the furnace.

Two heats are run off per day. The first is started with a cold furnace and tapped off in about 4.5 hours after lighting the burner. The second heat is started with a hot furnace and is poured in about 3.5 hours after starting the burner the second time.

The advantages derived in melting malleable iron with pulverized coal, as compared with hand-firing, are:

- (1) Increased economy. The ratio of coal to iron in hand firing, under the best conditions, was not over 1 to 2.5, while with pulverized coal the ratio is 1 to 4.5.
- (2) Owing to complete control of the melting conditions and of the speed of the operation, the heats may be tapped at exactly the time set in advance. This does not vary from day to day more than 5 minutes.
- (3) A hotter and more fluid iron is obtained which is very desirable in malleable iron practice. This cuts down the losses from misrun castings.
- (4) The cost of repairs to the furnace has been reduced approximately 50 per cent.
- (5) The labor saving, in running the furnace, is about 1½ men.

In 1919, a malleable melting air furnace was put in

	Hand-Fired Coal	Powdered Coal
Air pressure at furnace, oz.....	2 to 3	½ to 1
Diameter main blast pipe, in.....	18	15
Volume of main blast, cu.ft. per min.....	3,500	3,500
Time of melt, hours:		
Hot furnace.....	5.5	3.5-4
Cold furnace.....	6.5-7	4.5-5
Coal per ton of iron melted, lb.....	940	600

PERCENTAGE OF SAVING

Coal.....	31
Pig iron replaced by scrap.....	18
Time of melt.....	30
Labor.....	60
Skimming bars.....	30
Cost of repairs.....	29

In comparing the pulverized coal-fired furnace with the hand-fired furnace there are a number of other outstanding advantages which cannot be expressed in figures.

These have been summed up as follows:

- Less slag to dispose of, including all melted ash.
- Practically no ashes to dispose of.
- No cleaning clinkers from firebox.
- No grate bars. No top blast.
- No smoke at any time.
- More uniform analysis of castings.
- Cleaner furnace surroundings.
- Easier on workmen, making them more satisfied, as there is less poking, leveling and skimming.
- Decreased oxidation of metal.

It is suggested that in malleable iron foundries where it has not paid to pulverize the fuel required for annealing alone it should now be possible to use pulverized fuel on a sufficient scale to prepare it economically.

Enameled Products Research Laboratory

Layout of Departments, With Enumeration of Laboratory Equipment—Organization Involving Services of Ceramic, Chemical and Metallurgical Engineers in Manufacture and Development of Uses for Enameled Apparatus—Method of Control and Research Applied to Orders and Inquiries

By EMERSON P. POSTE

Director of Laboratories, Elyria Enameled Products Co., Elyria, Ohio

THE keen interest which has recently been taken in the relation of the research laboratory to industry, together with complimentary remarks which have been made by persons who have visited the Elyria Enameled Products Laboratory, have suggested that it might be worth while to present the manner in which the manufacture of enamel-lined equipment depends upon the research laboratory for meeting the demands of the trade.

The field served by enamel-lined equipment is very large, including all phases of the dairy industry, the

The department of ceramic engineering has supervision over the preparation as well as the processing of the enamel in the factory. Its particular duty is to see that a given piece of apparatus leaves the factory properly enameled. This involves the improvement of existing commercial formulas and the development of new ones.

The chemical engineering department functions in co-operation with the sales department in specifying the proper equipment to meet the conditions of a given inquiry and also in developing new uses of enamel-lined equipment.

The metallurgical department has to do with metallurgical problems in the factory, which include foundry control, selection of proper steel for the construction of equipment and the effect of the enameling operation on the metal in the apparatus.

EQUIPMENT

With these general features in mind, it will be of interest to consider in detail the laboratory and its equipment. Fig. 1 shows a floor plan of the building. In the front portion of the building are the laboratory offices and library, which includes a well chosen set of references bearing on the problems of interest to the organization.

The analytical laboratory, a corner of which is shown in Fig. 2, occupies the remainder of the front wing. This laboratory is thoroughly equipped for the analysis of iron and steel, enamel raw materials, enamels and the various substances which may be submitted by the chemical engineering department in connection with its work.

The engineering laboratories are found in the main portion of the building, ceramic engineering to the east

FIG. 1. FLOOR PLAN OF CHEMICAL LABORATORY

processing of edible fats and oils, the preparation of canned foods and beverages and the manufacture of various pharmaceutical and chemical products.

If the equipment supplied to the trade is to prove satisfactory, two fundamental requirements must be realized; the apparatus must be of such a quality from a mechanical point of view that it will stand up under the service to be met and it must be so designed as successfully to carry out the operations for which it is intended.

The laboratory plays a very important part in the realization of these fundamental requirements both as to the manufacturing of the equipment and the proper design to meet the specific purposes. Besides these routine matters, there are many research problems which constantly call for attention bearing on actual factory processes as well as the use of equipment.

The laboratory organization necessary to meet the above functions includes the following departments: Ceramic engineering, chemical engineering and metallurgical engineering. In addition to these, the analytical department serves the three other departments as occasion may demand.

FIG. 2. A CORNER OF THE ANALYTICAL LABORATORY

FIG. 3. A CORNER OF THE ENGINEERING LABORATORY

and chemical engineering to the west of the hall. The ceramic laboratories include a general laboratory in which are found various electric furnaces, drying ovens and miscellaneous equipment for the control and study of enameling operations, and a mixing table for the preparation of experimental enamel batches. A corner of this room is shown in Fig. 3. Adjacent to the general ceramic laboratory is a petrographic laboratory, equipped with the latest model of petrographic microscope and refractometer for the study of the optical properties of enamel raw materials and enamels. A corner of this room can be seen in the background of Fig. 4.

The furnace room, adjacent to the general ceramic laboratory, contains a complete experimental enameling plant. Experimental batches which have been mixed in the ceramic laboratory are smelted in the crucible furnace shown in Fig. 5. The frit obtained from this furnace is ground in Abbe and Patterson jar mills and the resulting enamel is sprayed onto the experimental ware by the use of a Paasche spraying equipment. The grinding and spraying apparatus are shown in Fig. 6.

The burning equipment consists of a 3-ft. muffle furnace, the front of which, together with the charging machine, is shown in Fig. 7. This department also includes various miscellaneous pieces of equipment, such as crushers and Rotap sieve shaker.

The laboratory pyrometric equipment consists of a Leeds & Northrup potentiometer, Leeds & Northrup

optical pyrometer, Thwing radiation pyrometer and Brown portable pyrometer. This equipment is used for checking factory pyrometric equipment as well as in connection with experimental work.

The equipment of the ceramic engineering department makes possible the experimental processing of any type of enamel which may be of interest, together with a thorough study of the physical and chemical properties of enamel raw materials and enamels.

The chemical engineering laboratories are equipped with the necessary apparatus for studying field problems from the initial to the semi-commercial stage. The equipment includes the usual glass and porcelain units and a variety of semi-commercial models of agitation, emulsification and similar apparatus.

In addition to various small enameled units, there are available in the laboratory a 2-gal. jacketed enamel-lined unit, an open-top 5-gal. enamel-lined kettle and two sets of semi-commercial vacuum pans.

Fig. 8 shows the steel vacuum pans so assembled as to make possible the processing of various materials under different methods of heating. The pan at the

FIG. 5. EXPERIMENTAL CRUCIBLE FURNACE

left is equipped with silver-plated copper coils as a heating medium and the one at the right with a steam jacket. The condenser and receiver are shown in the center. Either pan can be attached to the condenser and various types of agitating devices can be used as indicated on the pan at the right.

Fig. 9 shows the cast-iron jacketed vacuum pan with condenser and receiver. This particular unit is used in connection with problems involving mineral acids necessitating the use of the more acid-resisting cast-iron enamel. The vacuum requirements of the entire laboratory are served by a Crescent rotary vacuum pump with a capacity of 50 cu.ft. of free air per minute.

The chemical engineering department also has available for the testing of actual commercial units a portion of the testing floor of the factory and carries on such tests on full-sized units as may be desirable.

The metallurgical equipment includes such apparatus as is necessary for physical tests on the various materials of construction and metallographic studies in connection with the enameling operations. The work of this particular nature is done in the microphotography room opening off the chemical engineering laboratory.

FIG. 4. A CORNER OF THE PETROGRAPHIC LABORATORY

FIG. 6. GRINDING AND SPRAYING APPARATUS

The laboratory building also contains a store room and comfort room in which first aid work is given to factory employees.

THE LABORATORY AND THE FIELD

With this equipment in mind, we may assume that the reader will be interested in knowing how the laboratory functions in connection with an inquiry which may be received from the sales department.

The original information submitted to the salesman is turned over to the chemical engineering department for consideration. If there is on file a sufficient amount of information to cover the case, definite action is taken. It may be necessary, however, to carry on additional experimental work in the laboratory or to send a laboratory representative to the customer to make a more detailed study of his problem. If the laboratory comes to a definite conclusion as to the feasibility of furnishing the proposed equipment, it makes a report specifying the exact equipment which should be furnished for the case in hand, the engineering department co-operating in working out the actual design. If, on the other hand, the laboratory, through previous information or by further experiment, finds that enameled equipment would not satisfactorily serve the purpose in mind, a report to this effect is submitted to the sales department.

When the order is reached by the manufacturing department, it first goes to the laboratory, is correlated with previous experimental work on record, and the

FIG. 7. MUFFLE FURNACE AND CHARGING MACHINE

proper enamel to meet the requirements is specified. A memorandum goes to the ceramic engineering department with the specifications for inspection. This department is then responsible for the proper processing of the piece through the shop and the inspection thereof in accordance with the specifications received.

Records bearing on every specific piece of equipment include the composition of the metal used in the unit, the formula and actual batch number of the enamel, and the condition of the tank when finally inspected, as well as a full record of the specific information as to the intended use. Field observations in connection with the particular unit are correlated with these factory records later.

It will be of further interest to consider briefly some typical research problems which are at present on the laboratory schedule. The ceramic engineering depart-

FIG. 8. STEEL VACUUM PANS

ment is making a very thorough study of the properties of enamel raw materials and the general behavior of each when incorporated in an enamel mix. The chemical engineering department has recently obtained some intensely interesting data as to the action of metals on milk, bringing forth some very striking arguments against the use of metallic milk containers. The metallurgical department has recently demonstrated that the enameling operation furnishes a very thorough annealing of the oxyacetylene weld used in the fabrication of steel units.

The laboratory is under the direction of Emerson P. Poste, who was graduated in chemical engineering from Carnegie Institute of Technology in 1910 and after two years with that institute as instructor in chemistry assumed his connection with the laboratory.

Bryan A. Rice, who is in charge of the ceramic engineering department, was graduated from the department of ceramic engineering of Ohio State University in 1917. After two years of commercial experience

FIG. 9. CAST-IRON JACKETED VACUUM PAN WITH CONDENSER AND RECEIVER

with the company, he returned for post-graduate work in connection with certain problems of enamel technology.

The chemical engineering department is in charge of Max Donauer, who after his graduation from the department of chemical engineering of the University of Minnesota has had a considerable commercial experience along his line, including very responsible duties in charge of the Ordnance Control Laboratory of Philadelphia during the war. He has held his present position for the past two years.

In addition to the above heads of departments the laboratory staff includes several assistants who perform the analytical and other routine work.

Zinc Cyanide Plating Solutions

Zinc coatings furnish by far the best protection against corrosion of steel, and for this reason zinc plating or electrogalvanizing was extensively applied to all sorts of machinery during the war. Satisfactory zinc deposits can be secured from either sulphate or cyanide solutions, but the latter possess the advantage of "throwing" the deposit better into deep depressions or upon the surface of irregularly shaped articles. The cyanide solutions were, therefore, given first consideration in the investigations conducted by the Bureau of Standards. It is hoped later to extend this study to include the sulphate solutions. It was found that satisfactory zinc cyanide plating solutions can be made by using zinc oxide to replace part or all of the zinc cyanide formerly employed for this purpose.

Technologic Paper 195 of the Bureau of Standards describes the above work and gives formulas for satisfactory solutions and general directions for their use.

Book Reviews

CONCENTRATION BY FLOTATION. By T. A. Rickard. New York: John Wiley & Sons, Inc. 692 pp. Illus. Price \$7.

Just at the time that T. A. Rickard returned to San Francisco from London to assume the management and editorship of *Mining and Scientific Press*, flotation was assuming a position of importance in the United States. Mr. Rickard immediately perceived that here was just such an opportunity as, if taken hold of, would give his paper such renewed impetus as it appeared to him just then was so essential.

With this end no doubt largely in view, but also on account of his own keen personal interest in all subjects of vital importance to the profession, he made "flotation" the slogan of his journal and thus attracted to it, in advance of others, a series of interesting articles upon this new subject; his paper having become, for the time, the repository of its newly making literature. It was therefore most natural that such a series of articles as appeared in the *Press* should find more ready means of access in book form.

Two volumes comprising reproductions of these articles which had appeared in *Mining and Scientific Press* have been published previously. This third volume, however, is presented as more complete, and contains, besides twenty-two articles which were in the previous volumes, eighteen later articles. As the preface to this third states, it does not profess to be complete or final. The subject matter is somewhat confusing in its sequence of articles, as what is practically the same topic appears in widely separated chapters, by different writers and without apparent arrangement.

It would take one far beyond the limits of such a book review as this to attempt any comparison of one of these chapters with another, or to note differences and similarities of opinions given, or to discuss what the reviewer feels to be regrettable misconception as to some important matters. However this may be, it is a convenient collection of much that is most interesting, and references cited add greatly to its scope.

R. C. CANBY.

* * *

AMERICAN CHEMISTRY. By Harrison Hale. 215 pp., 63 illustrations. New York: D. Van Nostrand Co. Price, \$2.

Dr. Hale has chosen to review American chemistry in such a way as to interest both the layman and the student in the achievements of our chemical industry and its inviting possibilities for future developments. Considered from this point of view, his book must be regarded as a very creditable attempt to serve an excellent and worthwhile purpose. That it falls short of its goal in a number of outstanding instances is to be regretted, especially so when it is realized that some of its faults are inexcusable. In the first place there is abundant evidence of careless writing, loose construction and generally inefficient use of English. It is apparent, too, that the author has not been altogether successful in adopting the non-technical style, which is so essential if he is to attract and hold the interest of the general reader. There are many technical expressions and unfamiliar words which might well have been avoided or at least given some explanation for the benefit of the layman. If, however, we consider the second purpose of the book—namely, "for use either as collateral reading along with a course in general chemistry or as a short separate study"—some of reviewer's criticisms do not apply. Certainly, it is a laudable desire to acquaint the student with the industrial importance of the science he is studying. His interest in his immediate task is stimulated, his viewpoint is broadened, and, if he is a red-blooded American, his patriotism is stirred by the record accomplishments of American chemistry. The author has done much to encourage the student's interest in current literature and the technical press, and the frequent reference to these sources of information will undoubtedly prove very useful. Furthermore, the many well-chosen illustrations add materially to the value of the book.

S. D. KIRKPATRICK.

Current Events

in the Chemical and Metallurgical Industries

More Plants Resume Operations

Leather. The New Castle Leather Co., Wilmington, Del., has added about 100 men to its working force, increasing production to approximately 90 per cent of normal.

Rubber. The Firestone Tire & Rubber Co., Akron, Ohio, is increasing its working force with intention of developing production to a point of about 18,000 tires a day.

Acid. The Marion Extract Co., Chattanooga, Tenn., manufacturer of tanning extracts, resumed operations at its plant on Nov. 7, following a curtailment for some time.

Coke. The Domestic Coke Corp., Fairmont, W. Va., has resumed production on a basis of about 40 per cent of normal, following curtailment for a considerable time.

Ceramic. About 250 kiln drawers employed at East Liverpool, Ohio, potteries who recently declared a strike against a wage reduction of 7 per cent, have returned to work pending a settlement with employers.

Iron. The Ulster Iron Works has reopened its plant at Dover, N. J., following a shut-down dating from last spring. Substantial wage reductions have been placed in force. Puddlers heretofore receiving \$9 for a 10-hour day, will be paid \$5.50; and helpers \$4.01, as compared with \$6 when the plant closed.

The Reading Iron Co., Reading, Pa., has resumed production at its puddle furnaces at the Ninth St. mill, and seventeen units have been placed in service. The larger portion of the plant has been idle for a number of months.

The Carnegie Steel Co., Youngstown, Ohio, has blown in another blast furnace at its local mills, making four out of seven units now in service.

The United States Cast Iron Pipe & Foundry Co., Chattanooga, Tenn., has resumed operations at its local plant, following a shut-down since last January.

The Republic Iron & Steel Co., East Chicago, Ind., has opened its local plant, following a period of inactivity for about three months past. About 200 men will be employed at present, and which number will be increased gradually as conditions warrant.

Steel. The United States Steel Corporation, New York, N. Y., is now operating at about 51 per cent capacity at its various mills, the highest production record since last March. At one time in July a low point of 18 per cent of normal was reached.

The Bethlehem Steel Co., Bethlehem, Pa., has resumed operations at its 20-in. rolling mill at the Steelton, Pa., works, following a shut-down for several weeks through lack of orders.

The Carnegie Steel Co., Pittsburgh, Pa., is giving employment to about 5,600 men at its various plants at the present time, as compared with a normal working force of 6,800 men.

Metal. The International Silver Co., Meriden, Conn., has adopted an overtime operating schedule at its Factory L, Wallingford, Conn. With a 55-hour week in force, about 250 operatives will work four nights a week until 9 o'clock. A number of new workers are being employed.

Tinplate. The American Sheet & Tinplate Co. has resumed full operations at its Elwood, Ind., plant, placing twenty mills in service Nov. 7, with employment of about 1,500 men.

Laboratory Car for Brick Kiln Tests

Arrangements have been made in connection with the co-operative agreement between the associations of brick manufacturers and the Bureau of Mines to fit up a laboratory car which will be used in testing kilns at brick works. This will make possible a much more expeditious handling of this very necessary phase of the work and will permit its being done in a very thorough manner.

To Consider Chemical Warfare at Arms Conference

While the simple and direct proposal of Secretary of State Hughes probably will make it unnecessary for the Conference on the Limitation of Armament to consider the economic phases of international relationships, it is certain that chemical warfare will receive consideration. Seven members of the American advisory committee already have been designated to make a special study of the relation of chemical warfare to the limitation program. Carmi A. Thompson, of Cleveland, the general manager of the Great Northern Iron Ore Properties, was designated as chairman of the sub-committee. Other members are Mrs. Katherine Phillips Edson, John L. Lewis, Gov. John M. Parker, General Pershing, Admiral Rogers and Theodore Roosevelt. Mr. Parker is Governor of Louisiana; Mr. Lewis is president of the United Mine Workers of America. At the time of this writing, the other duties of the advisory committee had been such as to preclude any meeting of the Thompson sub-committee. For the same reason the technical staff of the American delegation has had no opportunity to discuss chemical warfare or any of the other subjects coming within its jurisdiction.

American Gas Association Meets in Chicago

The third annual convention of the American Gas Association met in Chicago during the week ended Nov. 12. General sessions were held each morning at the Congress Hotel, while the five sectional meetings were held during the afternoons in rooms at the Congress and Auditorium hotels. These sections are the accounting, commercial, publicity and advertising, the technical, and the manufacturers' section. At the same time exhibits of gas appliances and gas-plant apparatus were shown by the manufacturers in both the Elizabethan Room and the Florentine Hall of the Congress Hotel. Entertainment features of the convention included the president's reception, the annual banquet followed by a dance, arrangements for golf fans, and a trip to the new plant of the Chicago Byproduct Coke Co.

GENERAL SESSION

President Charles A. Monroe opened the general session with an address on the progress of the association. It was organized in June, 1918, in New York City to promote and develop the gas industry and effect the best service to the public. The year 1920 was the darkest for the industry and the strain has humbled every man in the business. This has been a great thing, because it has driven the members to seek co-operation. The gas industry was one of the first to feel the effects of tax exemption on government and state securities. The association has made progress in arousing public sentiment against tax on public utility securities. In co-operation with the National Electric Light Association and the American Electric Railway Association a committee has been organized to support the Smoot bill.

There is a general need as regards specifications for a general lowering of the calorific standard for national conservation of our fuel. Conservation of life in the industry through new resuscitation methods has been effected, and particularly good work has been done by the committee operating under the direction of Dr. Cecil Drinker, of Harvard University.

Increased cost of producing gas has called for increased rates if the utilities are to survive. The public understands the gas industry situation better than ever before. The association must continue to point out to the universities the need of technical men trained in the gas industry. The University of Michigan now has a 3-year course in

gas engineering. The Natural Gas Association of America should amalgamate with the American Gas Association, because in the course of time as the supply of natural gas becomes less, the problems of both associations will become identical and duplication may thereby be avoided. The reports of the various committees showed the association to be in good shape as regards its business affairs. It now has a surplus of \$92,849. Officers elected for the coming year were: President, D. D. Barnum, of Boston; vice-president, R. D. Brown, of Milwaukee, and treasurer, H. M. Brundage, of New York.

Among other talks of interest at the general session was one by R. P. Perry, vice-president of The Barrett Co., on "Why Should Gas Companies Sell Their Tar to Distillers Instead of Working It Themselves?" Mr. Perry pointed out the wide variations which exist in the physical and chemical properties of tars from different sources, and emphasized the difficulty of producing marketable tar and pitch products from the tar of a single gas plant.

Other speakers of note at the general session were: George B. Courtelyou, national counsel of the Consolidated Gas Co., New York; R. M. Searle, president of the Rochester Gas & Electric Corporation, and Samuel Insull, chairman board of directors, People's Gas Light & Coke Co., Chicago.

TECHNICAL SECTION

At the Wednesday afternoon session, M. E. Benesh presented a paper on "What Goes On in a Water-Gas Machine," in which he described an apparatus for indicating the percentage decomposition of steam during a run. Partially decomposed steam leaving the generator is passed at constant temperature (checked by a dry-bulb thermometer) over a wet-bulb thermometer. Since the dry-bulb temperature is constant, the wet-bulb thermometer may be graduated directly in per cent decomposition of steam.

A. W. Warner, as chairman of the committee on complete gasification of coal, presented a review of several methods of complete and partial gasification. A brief on the gas oil situation was submitted by the committee appointed to consider this subject. Results of tests on refractory materials for use in lining water-gas generators were given by the committee on refractory materials. In spite of the rather negative character of the results obtained to date, the committee stated that it was not pessimistic over the probability of finding more suitable refractories for generator linings than fireclay blocks.

On Thursday afternoon J. T. Griffin discussed a method of removing stoppages of rust in gas lines by the use of cylinders of compressed air at a pressure of 1,500 lb. per square inch. The committee report on the progress made in the research investigations on gas purification problems was supplemented by an excellent selected and annotated bibliography on gas purification. Another phase of purification was treated by W. A. Dunkley in a paper on "The Effect of Moisture on the Activity and Capacity of Iron Oxides for Gas Purification." Practical results in the removal of hydrogen sulphide by the Seaboard liquid process were described at length in a very interesting paper by F. W. Sperr, Jr., which will be treated more fully in a subsequent issue.

"Some Experiments With the Mixing of Different Gravity Gases in Holders" was the title of the first paper presented before the section on Friday. The author, H. E. Bates, called attention to the increasing importance of the problem of the proper mixing of gases, and gave curves showing the results of tests made with a small holder.

One of the most important reports presented at the meeting was that of the carbonization committee. The operators' section submitted standard carbonization data for nineteen plants. The low-temperature carbonization section reviewed the present status of carbonization at low temperature. This report will be considered in more detail in a subsequent issue. Eleven manufacturers of carbonizing apparatus reported in the builders' section, giving interesting data on recent improvements and new designs.

The report of the committee on the disposal of waste from gas plants closed the meeting of the technical section.

Postmaster General Hays Discusses the Tariff

In the course of an address before the Fifth Avenue Association in New York, Nov. 15, Will H. Hays, the Postmaster General, made significant references to the tariff situation. His utterance in some quarters at least is interpreted to mean that there will be no effort to hurry the enactment of the tariff bill. An extract from Mr. Hays' speech follows:

Before 1914 we were a debtor nation—the largest in the world. Today we are precisely the opposite. We are the largest creditor nation in the world. Just what is the effect of the enormous importance of this change in our economic and commercial position in relation to the rest of the world I do not pretend to know. I merely point out that no thorough or open-minded or candid consideration of the tariff question can be complete without including consideration of this new factor. Regardless of what an investigation of this point might reveal—omitting this factor altogether—it is a fact that to thoughtful men there must be approval of a certain hesitation and disposition to be cautious and a determination to be sure-footed in the consideration of the whole subject of the tariff. Conditions throughout the world are so chaotic that it's difficult to foretell exactly what is needed. The very basic condition on which a tariff is built—the cost of manufacturing in various European countries with relation to our own cost of manufacture and the value of the currency of the various European countries with relation to the value of our own currency—is at the present moment as fluctuating as quicksand. To build a dependable tariff on such a foundation is difficult, of course. It has been thought by many that we could overcome these handicaps by a device which is called American valuation and which provided that all customs duties shall be estimated upon the value of goods at the time when they arrive in the United States and in terms of American money. The Congress in a proper eagerness for information has made an appropriation of \$100,000 to investigate the device and otherwise determine what might be done to help us toward writing a permanent tariff. This was proper, but a much better arrangement and one which is very definitely in the mind of the administration for accomplishment, is to make the Tariff Commission a really useful and functioning institution which will constantly study the situation and with sufficient authority, which ought to be given it, be able to meet any and all conditions which obtain or emergencies which may arise. The work of the special investigation has been going on and with the adjustment of our international relations by the accomplishment of the steps which the President has in mind we may expect relief from some of the conditions of fluctuation and instability so that proper permanent tariff making is possible.

Washington Section Officers Selected

R. C. Wells, of the U. S. Geological Survey, will be president of the Chemical Society of Washington for the coming calendar year, as a result of the election of this section of the American Chemical Society, held on Nov. 10. Other officers selected were: J. B. Reed, secretary; H. W. Houghton, treasurer; W. D. Collins, R. B. Sossman, W. W. Skinner, W. M. Clark and William Blum, councilors; and C. W. Bacon, V. K. Chestnut, L. H. Adams, F. C. Cook, C. O. Appleman and R. O. E. Davis, members of executive committee. The past presidents of the section addressed the meeting during the course of the election on various interesting developments in their several fields and regarding some interesting events in the earlier history of the society and the Washington section.

New Gas-Fired Kiln to Be Demonstrated

Arrangements are being made for a number of demonstrations in this country of a new gas-fired kiln for ceramic products, and primarily pottery, invented by Arthur G. Shaw of the Shaw Glazed Brick Co., Ltd., Glasgow, Scotland. Mr. Shaw, who recently arrived in the United States, states that the new kiln shows a saving of from 66 to 85 per cent in fuel and about 30 per cent in labor. P. Wylie Rodger of the Gartgraig Fire Clay Co. and Walter Bakewell of the Cauldon Potteries are accompanying Mr. Shaw.

International Labor Conference Discusses White Lead and Anthrax Poisoning

Much discussion has resulted from the consideration of the question of prohibiting the use of white lead in painting, by the International Labor Conference, now in session in Geneva, at which thirty-nine governments and the workers' and employers' organizations of those countries are represented.

Early in the conference the question was referred to a commission which was to study the subject and prepare a report to the conference. According to cabled information received at the Washington office of the International Labor Office, this commission has now returned a majority report opposing the prohibition of the use of white lead in painting, and stating that it is the opinion of the commission that the prohibition is not necessary in the interests of the painters, nor desirable in the interests of the users or producers of white lead. The commission recommended a draft convention for the regulation of the use of white lead in painting, such as measures for avoiding danger from dust in dry scraping, dangers of spraying with white lead pigments, provision of adequate washing facilities for those using white lead pigments, etc.

A minority report was also presented by members of the commission, which calls for the complete prohibition, or at least for the prohibition in interior work, of the use of white lead in painting.

The question of the disinfection of wool infected with anthrax spores, which appears on the agenda of the conference, has been disposed of by the unanimous adoption of a resolution to refer this question to a special committee to be appointed by the governing body of the international labor organization. It was suggested in the resolution that the British Government be asked to nominate the chairman of this committee. The resolution further stated that "the International Labor Conference is of the opinion that the co-operation of the United States of America should be invited on this question."

Chemical Salesmen Meet in New York

The Salesmen's Association of the American Chemical Industry held a dinner meeting in New York on the evening of Nov. 15, at which a number of important matters of business were transacted. It was announced that the plan to organize local chapters was proceeding satisfactorily. It seemed wise and opportune for the New York members to organize as a chapter and accordingly this was done by electing the following officers: Ralph Dorland, of the Dow Chemical Co., chairman; George H. Short of Wilckes, Martin & Wilckes, secretary, and Spencer Levy, editor of the *American Perfumer*, treasurer.

Charles B. Hall, of the Cleveland-Cliffs Iron Co., chairman of the Cleveland local chapter, made a brief address expressing the spirit of good will and co-operation that the Cleveland members hold toward all other members of the association. Theodore R. L. Loud, of the New York Quinine & Chemical Works, Inc., gave a brief but inspiring review of some of the early characters and traditions of the medical chemical industry in this country. He mentioned specifically such men as Weightman, Rosengarten and Squibb. This was followed by an address by Saunders Norvell, of McKesson & Robbins, in which he gave the members of the association very helpful business advice.

New Chemical Companies Organized

During the month of October twenty-six new companies in the chemical, drug and affiliated fields were organized with a capitalization of \$50,000 or greater, as compared with the formation of thirty-five such companies in September. The October aggregate shows a combined capitalization of \$6,675,000, as against the September total of \$7,450,000. During the month of October a year ago the aggregate capitalization of new companies was \$4,825,000.

The first 10 months of the present year shows a combined authorized capitalization of \$98,515,000 for new chemical companies; in the corresponding period for 1920 the aggregate reached \$180,467,000.

Excess Varieties of Paving Brick Eliminated

An indication of what may be accomplished in the elimination of waste and of excess variety was had when manufacturers and consumers of paving bricks perfected an arrangement in a 2-hour conference whereby fifty-five varieties of paving brick were eliminated from the sixty-six styles now being manufactured. The meeting at which this was accomplished was held in Washington Nov. 15 under the auspices of the Department of Commerce. While shrinkage of clay and other ceramic phases of brick-making came in for some discussion in the matter of variations from the dimensions fixed as standards, these technical questions are to be handled by special committees now working in co-operation with the Bureau of Standards. Similar conferences are planned to consider other types of brick.

The work begun at the Washington conference is to be carried on by a committee to be composed of representatives of the following organizations: National Paving Brick Manufacturers Association, Chamber of Commerce of the United States, American Society of Civil Engineers, American Association of State Highway Officials, American Society of Municipal Improvement, American Society for Testing Materials, Federated American Engineering Societies, Bureau of Public Roads, Bureau of Standards.

Alloy Work Discussed

The work on alloys being done by the Bureau of Mines was reviewed at a meeting between bureau officials and the standing committee of the American Institute of Metals. It was decided that the standing committee would meet twice a year in the future at the Bureau of Mines. Those in attendance at the meeting were H. Foster Bain, director, Bureau of Mines; W. M. Corse, Monel Metal Products Corp.; R. B. Moore, chief chemist, Bureau of Mines; William B. Price, Scovill Manufacturing Co.; W. H. Bassett, American Brass Co.; R. J. Anderson, Bureau of Mines; L. W. Olson, Ohio Brass Co.; C. H. Bierbaum, Lumen Bearing Co.; George C. Stone, New Jersey Zinc Co.; W. R. Webster, Bridgeport Brass Co.; H. W. Gillett, Bureau of Mines; DeCourcy Browne; Paul D. Merica, International Nickel Co.; J. L. Jones, Westinghouse Electric & Manufacturing Co.; John F. Thompson, International Nickel Co.; William A. Cowan, National Lead Co.; Andrew Stewart, Bureau of Mines; Dorsey A. Lyon, Bureau of Mines; E. L. Mack, Bureau of Mines.

Directors' Meeting American Electrochemical Society

At a meeting of the directors of the American Electrochemical Society held in New York on Nov. 16, Dr. Colin G. Fink was elected secretary to fill the unexpired term of Dr. Joseph W. Richards, deceased. The directors received an exhaustive report of the finance committee and considered various ways and means for putting the society on a sound financial basis. From its inception the society has maintained dues at \$5, but it may be necessary to increase this sum in order to get more revenue. Temporarily an increase in revenue will be obtained by charging \$3 per annum instead of \$5 per annum for the bound volumes of the society's *Proceedings*, but a constitutional amendment will be initiated to increase the dues from \$5 to \$8. If this is accomplished, the price of bound volumes will be restored to \$5. The treasurer of the society was authorized to use his discretion in disposing of assets in the form of bonds to meet current expenses.

Further Hearings to Be Held on Water Pollution Bills

Recognizing that it has before it a very knotty problem and one likely to cause hardship to manufacturing enterprises, the Rivers and Harbors Committee of the House of Representatives has determined to hold further hearings on the various bills proposing remedies for the pollution of coastal waters and the waters of streams. The hearings are to be reopened on Dec. 7.

American Electrochemical Society Honors the Memory of Dr. Joseph W. Richards

The meeting of the New York Section of the American Electrochemical Society held at Rumford Hall Nov. 16, 1921, was devoted to addresses and reminiscences on the life and work of the late Dr. Joseph W. Richards, who had been the society's first president.

Dr. Charles Doremus, acting as chairman, introduced Acheson Smith, the president of the society, who related some of the outstanding incidents in the work of Prof. Richards as president and secretary of the American Electrochemical Society and expressed the gratitude due his memory for his ever active interest in the welfare and usefulness of the society.

DR. RICHARDS AS EDITOR AND AUTHOR

The work of Dr. Richards as an editor and author was outlined by H. C. Parmelee, editor of *CHEMICAL & METALLURGICAL ENGINEERING*. He commented on Dr. Richards' part in founding the monthly magazine, *Electrochemical Industry*, in 1902, and his activities as president of the Electrochemical Publishing Co. of Philadelphia, which published this magazine until the end of 1912, when it was purchased by the McGraw Publishing Co. During this period and even up to within a few days of his death, Dr. Richards made many valuable contributions to this magazine, which has since become *CHEMICAL & METALLURGICAL ENGINEERING*. In the field of authorship Dr. Richards contributed abundantly to the technical literature, the most widely known works being his book on Aluminum and the revised Metallurgical Calculations. Mr. Parmelee then related some intimate reminiscences of his early connection with Dr. Richards in editorial matters and referred to him as an indefatigable worker and an inspiration and example to all.

DR. RICHARDS AS PRESIDENT AND SECRETARY OF THE SOCIETY

Dr. Carl Hering, one of the founders of the society, gave a historical review of the conferences in Philadelphia among a handful of men enthusiastically interested in the growth of the electrochemical industry, which led to the foundation of the monthly *Electrochemical Industry* with Dr. Richards as president and Dr. E. F. Roeber as editor. He then outlined the history of the foundation of the Electrochemical Society with Dr. Richards as the first president. He spoke highly of the services rendered to the society by Dr. Richards, who, it is worth recording, was the only member twice honored with the presidency of the society, and his tireless work as secretary from 1907 to the time of his death.

Dr. Hering then conveyed the messages he had received from Dr. C. J. Reed, another member of the still living handful of founders of the society, and from C. O. Mailloux, the president of the American Institute of Electrical Engineers.

In the telegram, dated Nov. 13, from San Francisco, Dr. Reed said: "Distance prevents my attending the Joseph W. Richards memorial service. I desire to express through you my feeling of what must be the universal feeling that in the death of Dr. Richards the American Electrochemical Society has suffered the irreparable loss of one whose original interest and subsequent self-sacrificing devotion made possible the organization and perpetuation of the society."

Dr. Mailloux' message, dated Nov. 12, reads: "At the moment when I am leaving my office to go to the pier to take the steamer for Europe, I receive the announcement of the meeting which is to be held Nov. 16 in memory of the late Dr. J. W. Richards. This letter, which is dictated in haste and which will have to be signed for me by my secretary, has for its object to let you know that I will be with you in spirit and would have liked very much to have been able to be physically present at the meeting. I knew Dr. Richards very well indeed. My acquaintance with him ripened into friendship many years ago when I was a non-resident lecturer at Lehigh University. I had the greatest respect and admiration for him. It may be truly said of

him that he possessed learning, culture and refinement to the highest degree. In certain fields of knowledge which he made his own, he did splendid work which will long keep his memory green in the scientific world. Great as is the loss to the world, the loss to the friends who admired and loved him is much greater; in fact, it is irreparable."

DR. RICHARDS AS TEACHER, MAN AND ARTIST

Dr. W. S. Landis chose to speak on the subject of "Dr. Richards as a Teacher at Lehigh University." He reviewed the latter's life from the time when he came as a lad from England until he became instructor at the Lehigh University, and then gave an account of his great educational service, first as instructor and then for over thirty years as professor of metallurgy at the Lehigh University.

William Richards, the only son of Dr. Richards, spoke of his father in filial and touching appreciation. Dr. Richards' sister told with glowing enthusiasm some of her reminiscences of her brother as the artist and the lover of music and of all that is beautiful and artistically recreative.

Status of Chemists in the Navy

The recent revision of the salary and wage scale in the Navy brought into prominence what is regarded as the very unfortunate status of chemists in the Navy. Chemists as such are scarcely recognized by that department of the Federal Government. The chemists in the Navy service are rated in exactly the same way as are draftsmen, mechanics, blacksmiths and other artisans. They are treated as artisans on the per diem basis.

It is stated by those in close touch with the situation that the Navy has failed to recognize the increased importance of chemistry in warfare. The situation is very different in the War Department, which has a Chemical Warfare Service, in which a large number of chemists are employed, all of whom are given full professional status—exactly the same recognition accorded professional medical men in the Medical Corps.

Unemployment Diminishing and Fewer Inquiries Being Cancelled

Statistics compiled by the Engineering Agency, a technical employment bureau, show that the number of inquiries for technical help in manufacturing, construction, industrial and commercial work steadily decreased from February, 1920, to June, 1921, and since the low month of June has shown an increase. In other words, the average minimum was reached in June and a slow but comparatively steady increase has been in evidence since then. Also, during the declining period many employers were forced to cancel their inquiries due to the falling off of their work, whereas since June there have been very few inquiries cancelled.

Personal

C. H. BRANDES, formerly chief mechanical engineer and general purchasing agent of the American Metal Co., New York, and its domestic and foreign subsidiaries, has severed this connection and announces the opening of offices at 42 Broadway, New York, for the conduct of business on his own account.

NELSON COURTLANDT BROWN has returned to his former position as head of the Department of Forest Utilization, New York State College of Forestry, at Syracuse University.

G. G. CREWAN, who was mechanical engineer with E. I. du Pont de Nemours & Co., Wilmington, Del., is now plant manager for the Refractory Products Corporation, Wilmont, Va.

F. E. DODGE, formerly of The Barrett Co., has recently

been made vice-president and manufacturing manager for the Protexol Corporation, Kenilworth, N. J.

M. L. DOLT, formerly research chemist with the American Cotton Oil Co., Chicago, Ill., is now in charge of food colors and pharmaceuticals at the Calco Chemical Co., Bound Brook, N. J.

GEORGE V. DOWNING, formerly research chemist for I. P. Thomas & Son, Paulsboro, N. J., manufacturers of fertilizers, has become chief chemist for Leas & McVitty, Inc., and the Buena Vista Extract Co., Salem, Va., in the tanning extract departments.

DR. COLIN G. FINK, formerly director of the research laboratory of the Chile Exploration Co., has opened an office as consulting engineer at 101 Park Ave. Dr. Fink was also recently elected secretary of the American Electrochemical Society for the unexpired term of the late Prof. Joseph W. Richards.

KUNO B. HEBERLEIN, formerly president and general manager of the Penoles Mining Co., Mexico, a subsidiary of the American Metal Co., New York, announces that he has severed this connection and opened offices at 42 Broadway for the transaction of business on his own account.

J. W. KIMBALL, formerly research chemist at the Delta Laboratory, Arlington, N. J., has joined the staff of the National Aniline & Chemical Co., Marcus Hook, Pa.

R. B. MOORE, chief chemist of the Bureau of Mines, addressed the New Jersey Chemical Society at Newark on Nov. 14. He discussed the chemical work of the Bureau of Mines and reviewed the work which has been done on helium.

H. C. PARMELEE addressed the Chicago section of the American Chemical Society Nov. 18 on "The Technical Paper and Its New Relation to Industry." Mr. Parmelee also addressed the students of the chemical department of Northwestern University, at Evanston.

R. T. STULL, superintendent of the Bureau of Mines Ceramic Station at Columbus, Ohio, conferred last week in Chattanooga with officials of the Central of Georgia R.R. concerning the co-operative work being done on Georgia kaolins.

LOUIS J. TROSTEL, who for the past two years has been stationed with the U. S. Bureau of Mines at Pittsburgh, Pa., engaged on problems relating to industrial gases and dusts, resigned on Nov. 1 to take a position with the Bureau of Chemistry as assistant chemical engineer. He will be associated with the work of that bureau on the chemical problems relating to explosions from starch and other carbonaceous dusts.

PROF. ARTHUR L. WALKER, professor of metallurgy in the School of Mines of Columbia, was elected a member of the board of Engineering Foundation. Prof. Walker succeeds the late Joseph W. Richards of Lehigh University, who died recently. He will represent the American Institute of Mining and Metallurgical Engineers on the board of the Foundation.

DR. E. R. WEIDLEIN, director of the Mellon Institute, Pittsburgh, spoke before the Philadelphia section of the American Chemical Society Nov. 17 on savings in fuel effected by covering pipes with insulating material.

Obituary

FRANK A. LANE, whose formula made possible quantity manufacture of "mag," a chemical necessary to the perfection of gas masks for American troops in the World War, died in St. Mary's Hospital, Passaic, N. J., Nov. 16, following an operation for an intestinal ailment. His home was 26 Oak Crest Place, Nutley, N. J. Mr. Lane was an expert practical chemist, assistant to the president of the Kalbfleisch Corporation, with offices in New York. After the armistice the Government Bureau of Information declared that no American soldier was killed by gas while using an American mask, according to a statement issued recently by the Kalbfleisch Corporation.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Nov. 21, 1921.

After an interruption of a series of holidays, the chemical market has become settled again and improvement along the entire list was noted. Business is not being booked for large quantities, but the volume of small orders is quite large and this in itself is a very encouraging feature. Leading consumers have shown some inclination toward contracts over next year and are eager to receive shipments on standing contracts. Increased activity has recently been noted at some of the more important chemical plants. Offerings on spot have noticeably diminished, with prices all around well maintained. Present railroad conditions have led leading factors to believe that the remainder of the year will find the chemical market quite active. Price changes during the week have not been of any special importance. Caustic soda and soda ash have remained rather quiet, with ash sales a fraction lower for carload lots. Bichromate of soda retained its former price and found occasional buyers at this level. Bleaching powder continued to move steadily and indications point to a normal market on this commodity for the rest of the year. Cream of tartar is very scarce on the spot market and prices are well sustained around the recent advance. Barium chloride is another chemical that has shown a remarkable comeback, with shipment material practically unobtainable. Yellow prussiate of soda is somewhat easier on spot, but shipment material is still commanding a premium.

CHEMICALS

Bichromate of soda consumers are buying spot goods at 8@8½c. per lb. The demand is chiefly for small quantities and this has kept the general market in a steady position. Imported *chlorate of potash* has been offered in the open market at prices ranging from 5½@6c. per lb. Domestic producers are still quoting unchanged figures and report a better inquiry from new directions. The call for imported goods has been decidedly better in the past week. Sales of imported *caustic potash*, 88-92 per cent, were reported at 5¾@6c. per lb. on spot. Shipment material was offered at 5½c. per lb. Orders have reached the market in better volume for small quantities, with the bulk of imported shipments going to consumers holding large contracts. *Caustic soda* was offered in various directions at 4c. per lb. f.a.s. New York. There were sales reported down to \$3.90 per 100 lb. for carload quantities and up to \$4.15 for lesser lots. Although prices have eased up somewhat, leading factors stated that the inquiry was fairly active with buyers' views a shade under the general quotations. Producers of *sal soda* offered spot material a trifle lower. A fair inquiry was reported, with prices ranging from \$1.80@\$2 per 100 lb., according to seller and quantity. Spot *prussiate of soda* was offered a fraction lower and interest was not as keen as a few weeks ago. There were sellers offering imported material at 14¾@14½c. per lb. Shipment material was quoted at 14½c. per lb. Conditions in *nitrite of soda* continued somewhat dormant with an occasional sale recorded at 6¾c. per lb. The regular quotation heard around the trade ranges from 6¾@7c. per lb. There were some large holders that intimated shading on round lot business. Light *soda ash* in single bags moved at \$2@\$2.10 per 100 lb. There were rumors of sales down to \$1.95 for carload quantities. Barrels were sold at \$2.35@\$2.45 per 100 lb., according to quantity and seller. Producers of *acetate of lime* are taking on business at 1¾c. per lb. This is the lowest price recorded on this commodity since the beginning of the year. Prices on *barium chloride* continued to show a stronger tendency and it is very doubtful if much spot material can be purchased. Shipment figures are quoted higher with \$55 per ton heard as the minimum selling price. Spot quotations range from \$58@\$65 per ton. Sellers of *barium nitrate* report sales at 7½c. per

lb., with a general quotation of 7½@8c., depending on quantity. The market is rather quiet and devoid of any special features. Spot *cream of tartar* is very scarce and doubt is expressed among leading factors of domestic material if better than 28c. per lb. can be done on imported goods. Prices range all the way up to 30c. Imported *sulphide of soda*, fused, was offered at 4½c. per lb. Consumers are showing a moderate interest at the lower figure and sales are reported in better volume. Sellers of *aluminum sulphate* reported a better inquiry, with sales recorded at 2¾c. per lb. for the iron free variety. Shipment material was quoted at 2½c. per lb. The commercial variety brought 1¾c. per lb.

COAL-TAR PRODUCTS

The coal-tar products market during the past week has been practically without any noticeable features, although prices throughout the list were well maintained. The garment strike has meant a setback to manufacturers of fur dyes and also to several textile mills. Hope is expressed, however, of a speedy settlement and producers seem optimistic about the general outlook. The extension of the emergency tariff has had a stabilizing influence on many consumers who had been doubtful about future protection for the industry and there is a more pronounced tendency to take on forward commitments at right prices. The demand for phenol has eased off a bit, but prices are being held firm. *Benzene* production is increasing as the steel output continues to grow. Refiners are quoting 27@33c. per gal., but are accepting business for future delivery only. Consumers seem more optimistic about their requirements and are now fairly well assured that their contracts will be filled. Resale lots are almost impossible to locate. Although buying on *phenol* has not been as active as a week ago, the general tone of the market is strong and prices are being well maintained at 10c. per lb. and upward for prime white crystals. There were some sales recorded at slightly lower prices for round lots, but 10c. seemed to be the general quotation. A moderate amount of business is being done in *alpha naphthol*, but buyers do not feel inclined to purchase in bulk lots. The crude is held at \$1.10 per lb., and the refined variety is quoted at \$1.25 per lb. Resale stocks of *aniline salt* are light and makers are firm at 24@26c. per lb. with a fair demand reported. Producers of *benzyl chloride* are firm at 20@25c. per lb. for the technical and 25@30c. per lb. for the refined. Demand for *diethyl-aniline* is fairly good and as first hands practically monopolize the market, prices are being held at \$1@1.10 per lb. A fair amount of business is passing in *benzoic acid* at 50@60c. per lb. for the technical and 62@65c. per lb. for the U.S.P. grade. Makers are holding figures at these levels. Producers of *H acid* are asking \$1@1.10 per lb., but sales have been made below these prices. Competition among sellers remain quite keen and has kept some producers out of the market. Competition among sellers of *paranitraniline* is resulting in price shading and sales down to 75c. per lb. were made during the week. Resale stocks have been cleared from the market and makers seem to have things well lined up.

The Chicago Market

CHICAGO, Nov. 18, 1921.

There has been but little change in the general condition of the chemical market in this section during the past two weeks. Practically all factors are enjoying a good volume of business, and with a few exceptions, prices are quite firm. The teamsters' strike delayed deliveries for a couple of days this week, but now everything is moving smoothly. It is noticeable that stocks of quite a few items are getting low and no one seems overstocked on anything.

GENERAL CHEMICALS

Caustic soda is very firm with only a moderate supply available on spot. The ground, 76 per cent, is offered at \$4.75@\$5 per 100 lb. and the solid at \$4.25@\$4.50. *Soda ash* is moving in a fair way and supplies are available at \$2.60 per 100 lb. for barrels. *Ammonium chloride* is very firm, with supplies scarce. It is doubtful if 8½c. per lb. on the white granulated could be bettered on material for

immediate delivery. *Barium chloride* is moving in a routine way at \$60@\$65 per ton for the imported white material. *Carbon tetrachloride* is in good demand, with 11c. per lb. the general quotation. *Carbon bisulphide* is very firm, with supplies light. The lowest offer noted for spot material was 7½c. per lb. in drum lots. *Formaldehyde* is very quiet and is quoted generally at 12c. per lb. for barrels. It is very possible that this price could be slightly shaded with firm business. *Glycerine* prices were advanced this week by refiners to 14½c. per lb. for drums. There was no noticeable large movement of this material. *Iron sulphate* is steady, with a fair demand at \$1.75 per 100 lb. *Epsom salts* are quiet and unchanged as to price. The U.S.P. material is offered by first hands at 2¾c. f.o.b. warehouse. *Lead acetate* is quiet, with supplies available at 12½c. for the white granulated.

The bichromates are steady, with only moderate supplies available. The *potassium bichromate* is quoted at 14c. per lb. and the *sodium* at 8½@9c. *Caustic potash* is enjoying a fair demand and is available at 6½c. per lb. for the 88-92 per cent material. *Bicarbonate of soda* continues to move in a fair way at \$2.60 per 100 lb. The demand for *hyposulphite of soda* has fallen off somewhat, but the price is unchanged at \$4.05 per 100 lb. for the pea crystals. *Zinc chloride* is in fair demand and a wide variety of prices is quoted, ranging from 7½c. to 11c. for the granulated in casks.

ACIDS

There were no new developments in the acid markets during the past two weeks, the prevailing tone being firm. *Acetic acid* is in fair demand, the 28 per cent commercial being offered at \$2.50 per 100 lb. in barrels. *Glacial acetic* is not moving so well, although there is a noticeable improvement. Prices are quoted ranging from 9@10½c. per lb., depending on quantity and seller. *Oxalic acid* is moving in a fair way at 16@17c. per lb. The heavy acids are moving in a satisfactory way, according to the producers, and are very firm as to price. *Muriatic acid* is quoted in carboys at 1½c., with the same price for *sulphuric*.

VEGETABLE OILS

There is only a fair movement of linseed oil and supplies are plentiful. The boiled oil in 10-bbl. lots is quoted today at 74c. per gal. and similar quantities of the raw at 72c.

NAVAL STORES

Business in the naval stores market is good and most factors report a satisfactory volume. *Turpentine* is moving in a fair way at 80c. per gal. in 5-drum lots. The *rosin* market is in a fair shape and the "H" grade is quoted at \$7.90 per 280 lb. for less than carlots.

The Iron and Steel Market

PITTSBURGH, Nov. 18, 1921.

Buying of steel products has decreased somewhat and prices are a trifle softer. There is merely a continuation of the new trend that developed at about the middle of October, not so much a decreasing in demand as an arrest of the increase that had been practically continuous for four months.

Fundamental conditions affecting the steel market have not changed for the worse, and in one respect there is an improvement, in that railroad buying on a scale that amounts to something has begun. Superficially the steel market presents an unfavorable appearance, but the condition results from two factors to which no one can object, one being that the increase in demand that resulted from the gradual depletion of stocks ended because the stocks were all liquidated, the other being that requirements of buyers always fall off somewhat toward the close of the year.

The requirements of the country have not decreased and there is no accumulation of steel to be worked off. All the evidence is that the steel made and shipped in recent weeks was actually needed by buyers for their current operations. As long as that is the case the steel industry has not lost ground.

A few thousand freight cars have been contracted for in the past 10 days, and more are in the market. Undoubtedly all orders as placed will be for prompt execution, causing

an immediate demand upon the steel mills for plates and other materials. The absence of car buying for so long a time past has not been due entirely to lack of funds, an important factor having been the impossible prices once asked for cars. Prices of cars are now moderately well liquidated, by car shop wages coming down and labor becoming more efficient, by prices of the various appurtenances getting into reasonable bounds and by steel prices declining farther. Nearly all of the decline in steel prices occurred months ago. Plates for car building would not have cost more than \$5 a ton more on Aug. 1 than they cost now, and that is a small item considering that an ordinary car had advanced from less than \$800 in 1914 to \$3,500 or thereabout in 1920.

Steel ingot production is at a rate between 40 and 45 per cent of capacity, there having been little if any decrease thus far from the 44 per cent rate shown for the month of October. A slight decrease from now to the end of the year is not an improbability, but a rate below 35 per cent is not to be expected. The 20 per cent rate seen last July was a special phenomenon, due to buyers liquidating stocks. Nothing of the sort can occur again unless buyers pile up stocks again.

Naturally there are predictions of decided improvement in the steel trade within the next few months. It has been said that one cannot really foresee the future of the steel industry more than about 6 months ahead, hence when demand is poor one has no reason to allow more than 6 months for a decided improvement. What is reasonably certain is that no very great improvement is to be expected before Feb. 1, because December and January are normally dull on account of the season.

STEEL PRICES

The slight sagging tendency noticed in steel prices, considered as a whole, in the past few weeks is a trifle more pronounced, and prices may be said to have distinctly softened in the past week, although no clear-cut declines have occurred. In not a few commodities it can be said that a carload can now be bought at the price it would have required a 500-ton inquiry to bring out a fortnight ago. Of the entire tonnage of bars, shapes and plates sold in the past week the average was probably nearer 1.60c. than 1.50c., some carload business being done at above 1.60c. In sheets the shading of 3c. for black and 4c. for galvanized is more general, and now it sometimes extends beyond \$2 a ton. On a very attractive order 2.75c. and 3.75c. are distinct possibilities, these being prices that were done freely before the advance at about the middle of September, \$5 a ton.

Tubular goods lists of Sept. 16 are being shaded by the majority of independents. A little shading developed soon after the reduced lists of that time were issued, and this shading has become more widespread rather than deeper. The leading interest maintains the list prices, with the usual qualification as to line pipe. Demand for tubular goods has increased somewhat in the past two or three weeks, in contrast with the condition in steel products generally.

PIG IRON AND COKE

Pig iron, long presenting a stagnant market, is now showing a disposition to yield in price whenever any competitive business of importance arises. Southern foundry has dropped from \$19 to \$18 Birmingham. In the local market, a buyer of a few hundred tons of foundry secured a price of \$20.50 valley, the market previously having been largely nominal at \$21. Basic is still quoted by furnaces at \$19 valley, but resale iron seems to be available at enough below this to attract orders away from furnaces. Bessemer is steady at \$20 valley, the price for more than three months.

Connellsville coke prices have weakened on account of an obvious overproduction, due to operators blowing in ovens on a too optimistic appraisal of the increase in demand, and in the past two weeks merchant ovens have been returning to the idle list. Spot coke is about \$3@3.15 for furnace and \$4@4.50 for foundry, being off in the week 10c. or 15c. in furnace and 25c. in foundry.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	—	\$0.40 - \$0.45
Acetone.....lb.	\$0.12½ - \$0.12½	.13 - .13½

Bleaching powder (see calc. hypochlorite).....	—	—
Blue vitriol (see copper sulphate).....	—	—
Borax (see sodium borate).....	—	—
Brimstone (see sulphur, roll).....	—	—
Bromine.....lb.	.27 - .28	.28½ - .30
Calcium acetate.....100 lbs.	1.75 - 2.00	—
Calcium carbide.....lb.	.04½ - .04½	.05 - .05½
Calcium chloride, fused, lump.....ton	23.50 - 24.00	24.50 - 25.50
Calcium chloride, granulated.....lb.	.01½ - .02	.02½ - .02½
Calcium hypochloride (bleach'g powder) 100 lb.	2.25 - 2.30	2.35 - 3.00
Calcium peroxide.....lb.	—	1.40 - 1.50
Calcium phosphate, tribasic.....lb.	—	.15 - .16
Camphor.....lb.	—	.85 - .90
Carbon bisulphide.....lb.	.06½ - .06½	.07 - .07½
Carbon tetrachloride, drums.....lb.	.10½ - .10½	.11 - .12
Carbonyl chloride, (phosgene).....lb.	—	.60 - .75
Caustic potash (see potassium hydroxide).....	—	—
Caustic soda (see sodium hydroxide).....	—	—
Chlorine, gas, liquid-cylinders (100 lb.) lb.	.08 - .09	.09½ - .10
Chloroform.....lb.	—	.40 - .43
Cobalt oxide.....lb.	—	2.00 - 2.10
Copperas (see iron sulphate).....	—	—
Copper carbonate, green precipitate.....lb.	.20 - .20½	.21 - .22
Copper cyanide.....lb.	—	.50 - .62
Copper sulphate, crystals.....lb.	.05 - .05½	.05½ - .06
Cream of tartar (see potassium bitartrate).....	—	—
Epsom salt (see magnesium sulphate).....	—	—
Ethyl Acetate Com. 85%.....gal.	—	.80 - .90
Ethyl Acetate pure (acetic ether, 98% to 100%).....gal.	—	.95 - .12½
Formaldehyde, 40 per cent.....lb.	.11 - .11½	.11½ - .12½
Fusel oil, ref.....gal.	—	2.50 - 3.00
Fusel oil, crude.....gal.	—	1.50 - 1.75
Glauber's salt (see sodium sulphate).....	—	—
Glycerine, C. P. drums extra.....lb.	—	.14½ - .15
Iodine, resublimed.....lb.	—	3.50 - 3.60
Iron oxide, red.....lb.	—	.12 - .18
Iron sulphate (copperas).....ton	18.00 - 19.00	20.00 - 23.00
Lead acetate.....lb.	—	.10½ - .12½
Lead arsenate, powd.....lb.	.15 - .15½	.15½ - .16½
Lead nitrate.....lb.	—	.15 - .20
Litharge.....lb.	.07½ - .08	.08½ - .09
Lithium carbonate.....lb.	—	1.40 - 1.50
Magnesium carbonate, technical.....lb.	.08 - .08½	.09 - .10
Magnesium sulphate, U. S. P.....100 lb.	2.50 - 2.75	—
Magnesium sulphate, technical.....100 lb.	—	1.10 - 1.75
Methanol, 95%.....gal.	—	.66 - .68
Methanol, 97%.....gal.	—	.70 - .72
Nickel Salt, double.....lb.	—	.12 - .12½
Nickel salt, single.....lb.	—	.14 - .14½
Phosgene (see carbonyl chloride).....	—	—
Phosphorus, red.....lb.	.40 - .41	.42 - .45
Phosphorus, yellow.....lb.	—	.30 - .35
Potassium bichromate.....lb.	.11 - .11½	.11½ - .12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$.04 - \$.05	\$0.28 - \$0.30
Potassium bromide, granular..... lb.	.15 - .16	.15 - .20
Potassium carbonate, U. S. P..... lb.	.04 - .04	.17 - .20
Potassium carbonate, 80-85%..... lb.	.04 - .04	.05 - .05
Potassium chlorate, crystals..... lb.	.06 - .06	.07 - .12
Potassium cyanide..... lb.	.05 - .06	.40 - .45
Potassium hydroxide (caustic potash)..... lb.	.05 - .06	.06 - .08
Potassium iodide..... lb.	.07 - .07	2.60 - 2.75
Potassium nitrate..... lb.	.07 - .07	.08 - .09
Potassium permanganate..... lb.	.19 - .20	.21 - .22
Potassium prussiate, red..... lb.	.28 - .29	.29 - .30
Potassium prussiate, yellow..... lb.	.21 - .21	.21 - .22
Rochelle salts (see sodium potas tartrate)		
Sal ammoniac (see ammonium chloride)		
Salt soda (see sodium carbonate)		
Salt cake (bulk)..... ton	20.00 - 22.00	
Silver cyanide..... oz.	1.35 - 1.38	
Silver nitrate..... oz.	.46 - .47	
Soda ash light..... 100 lb.	2.00 - 2.10	2.15 - 2.50
Soda ash, dense..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate..... lb.	.04 - .04	.04 - .05
Sodium bicarbonate..... 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium bichromate..... lb.	.08 - .08	.08 - .08
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.04 - .05	.05 - .06
Sodium borate (borax)..... lb.	.05 - .06	.06 - .07
Sodium carbonate (salt soda)..... 100 lb.	1.80 - 1.90	2.00 - 2.20
Sodium chlorate..... lb.	.07 - .07	.08 - .08
Sodium cyanide..... lb.	.28 - .28	.29 - .30
Sodium fluoride..... lb.	.11 - .12	.12 - .14
Sodium hydroxide (caustic soda)..... 100 lb.	4.00 - 4.10	4.15 - 4.50
Sodium hyposulphite..... lb.	.06 - .07	.07 - .07
Sodium nitrite..... lb.	.25 - .26	.27 - .30
Sodium peroxide, powdered..... lb.	.04 - .04	.04 - .05
Sodium phosphate, dibasic..... lb.	.14 - .14	.14 - .15
Sodium potassium tartrate (Rochelle salts) lb.	.95 - 1.00	1.10 - 1.25
Sodium silicate, solution (40 deg.)..... 100 lb.	2.30 - 2.40	2.45 - 3.00
Sodium silicate, solution (60 deg.)..... 100 lb.	1.50 - 1.75	2.00 - 2.25
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	.04 - .04	.05 - .05
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.03 - .03	.04 - .04
Sodium sulphite, crystals..... lb.	.13 - .14	.14 - .20
Sodium sulphite, powdered..... lb.	.05 - .05	.05 - .06
Sulphur chloride, red..... ton	18.00 - 20.00	
Sulphur, crude..... lb.	.08 - .08	.09 - .10
Sulphur dioxide, liquid, cylinders extra..... lb.		2.25 - 3.10
Sulphur (sublimed), flour..... 100 lb.		2.00 - 2.75
Sulphur, roll (brimstone)..... 100 lb.	.09 - .09	.09 - .10
Tin bichloride..... lb.	.16 - .16	.17 - .17
Tin oxide..... lb.	.09 - .09	.09 - .10
Zinc carbonate, precipitate..... lb.	.42 - .44	.45 - .47
Zinc chloride, gran..... lb.	.11 - .11	.11 - .12
Zinc cyanide..... lb.	.07 - .07	.08 - .09
Zinc dust..... lb.	3.00 - 3.25	3.30 - 3.50
Zinc oxide, XX..... lb.		
Zinc sulphate..... 100 lb.		

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.27 - .30
Aniline oil, drums extra..... lb.	.18 - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.35 - 1.45
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.62 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.75 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.30 - .34
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .17
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.00 - 1.10
Dimethylaniline..... lb.	.45 - .60
Dinitrobenzene..... lb.	.23 - .27
Dinitrochlorobenzene..... lb.	.20 - .25
Dinitronaphthalene..... lb.	.30 - .35
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, ear lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.00 - 1.10
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monochlorobenzene..... lb.	1.65 - 1.70
Naphthalene crushed, in bbls..... lb.	.06 - .08
Naphthalene, flake..... lb.	.06 - .08
Naphthalene, balls..... lb.	.08 - .09
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80
Para-dichlorobenzene..... lb.	.12 - .15
Paranitroaniline..... lb.	.75 - .80
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50

Phenol, U. S. P., drums..... lb.	.10 - .12
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.00 - 2.25
Salicylic acid, tech., in bbls..... lb.	.20 - .21
Salicylic acid, U. S. P..... lb.	.22 - .23
Salol..... lb.	.70 - .72
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .35

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.20 - \$0.21
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.34 - .38
Candellila wax..... lb.	.25 - .25
Carnauba, No. 1..... lb.	.45 - .46
Carnauba, No. 2, North Country..... lb.	.23 - .23
Carnauba, No. 3, North Country..... lb.	.14 - .15
Japan..... lb.	.21 - .21
Montan, crude..... lb.	.04 - .04
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 - .04
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 125 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 133-135 m.p..... lb.	.05 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 - .06
Stearic acid, single pressed..... lb.	.09 - .09
Stearic acid, double pressed..... lb.	.09 - .09
Stearic acid, triple pressed..... lb.	.10 - .10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.80 - 5.80
Rosin E-I..... 280 lb.	5.85 - 5.90
Rosin K-N..... 280 lb.	6.40 - 6.85
Rosin W. G.-W. W..... 280 lb.	7.10 - 7.30
Wood rosin, bbl..... 280 lb.	6.25 - .
Spirits of turpentine..... gal.	.82 - .
Wood turpentine, steam dist..... gal.	.80 - .
Wood turpentine, dest. dist..... gal.	.78 - .
Pine tar pitch, bbl..... 200 lb.	. - 6.00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	. - 10.50
Retort tar, bbl..... 500 lb.	. - 10.50
Rosin oil, first run..... gal.	.36 - .
Rosin oil, second run..... gal.	.39 - .
Rosin oil, third run..... gal.	.46 - .
Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	\$1.90 - .
Pine oil, pure, dest. dist..... gal.	1.50 - .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 - .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 - .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 - .
Pine tar, ref., thin, sp.gr., 1.080-1.060..... gal.	.35 - .
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 - .
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 - .
Pinewood creosote, ref..... gal.	.52 - .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 - .
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 - .
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 - .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 - .

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.60 - 2.90
Blood, dried, f.o.b., N. Y..... unit	4.00 - .
Bone, 3 and 50, ground, raw..... ton	30.00 - 32.00
Cyanamide, f.o.b. works..... unit	4.50 - .
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 - 3.00
Nitrate soda..... 100 lb.	2.40 - 2.45
Tankage, high grade, f.o.b. Chicago..... unit	3.00 - 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 - 6.50
Tennessee, 78-80 p.c..... ton	8.50 - 9.00
Potassium muriate, 80 p.c..... ton	37.00 - 40.00
Potassium sulphate..... unit	1.00 - 1.10

Crude Rubber

Para—Upriver fine..... lb.	\$0.23 - .23
Upriver coarse..... lb.	.13 - .14
Upriver caucho ball..... lb.	.13 - .14
Plantation—First latex crepe..... lb.	.18 - .18
Ribbed smoked sheets..... lb.	.18 - .18
Brown crepe, thin, clean..... lb.	.18 - .
Amber crepe No. 1..... lb.	.19 - .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 - \$0.10
Castor oil, AA, in bbls..... lb.	.11 - .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 - .13
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .09
Cocoonut oil, Cochon grade, in bbls..... lb.	.10 - .10
Corn oil, crude, in bbls..... lb.	.09 - .09
Cottonseed oil, crude (f. o. b. mill)..... lb.	.06 - .07
Cottonseed oil, summer yellow..... lb.	.08 - .08
Cottonseed oil, winter yellow..... lb.	.09 - .09

Linseed oil, raw, car lots (domestic)	gal.	.67	—	.68
Linseed oil, raw, tank cars (domestic)	gal.	.62	—	.63
Linseed oil, in 5-bbl lots (domestic)	gal.	.70	—	.71
Olive oil, Denatured	gal.	\$1.15	—	\$1.20
Palm, Lagos	lb.	.07 ³ / ₄	—	.08
Palm, Niger	lb.	.06 ³ / ₄	—	.06 ¹ / ₂
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08	—	.08 ¹ / ₂
Peanut oil, refined, in bbls.	lb.	.11 ¹ / ₂	—	.11 ³ / ₄
Rapeseed oil, refined in bbls.	gal.	.84	—	.86
Rapeseed oil, blown, in bbls.	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.08 ³ / ₄	—	
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.07 ¹ / ₂	—	

FISH

Light pressed menhaden	gal.	\$0.40	—	
Yellow bleached menhaden	gal.	.42	—	
White bleached menhaden	gal.	.45	—	
Blown menhaden	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$23.50	—	28.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	20.00	—	24.00
Barytes, crude, 88% @ 94% ba., Kings Creek	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri	net ton	7.00	—	
Blanc fixe, dry	lb.	.04	—	.04 ¹ / ₂
Blanc fixe, pulp	net ton	45.00	—	55.00
Casein	lb.	.07	—	.10
Chalk, Precipitated, domestic, extra light	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, domestic, light	lb.	.04	—	.04 ¹ / ₂
Chalk, Precipitated, domestic, heavy	lb.	.03 ³ / ₄	—	.04
Chalk, Precipitated, English, extra light	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, light	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, dense	lb.	.04	—	.04 ¹ / ₂
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	13.00	—	20.00
China clay (kaolin), imported, lump	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.	net ton	18.00	—	
Fullers earth, imported, powdered	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality	lb.	.06	—	.07
Graphite, Ceylon chip	lb.	.04 ¹ / ₂	—	.05
Graphite, high grade amorphous crude	lb.	.00 ³ / ₄	—	.02 ¹ / ₂
Kieselguhr, f.o.b. mines, Cal.	per ton	40.00	—	
Kieselguhr, f.o.b. N.Y.	per ton	55.00	—	60.00
Magnesium, calcined	per ton	60.00	—	65.00
Pumice stone, imported	lb.	.03	—	.40
Pumice stone, domestic, lump	lb.	.05	—	.05 ¹ / ₂
Pumice stone, domestic, ground	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore	net ton		—	10.00
Quartz (acid tower) 1 ¹ / ₂ @ 2 in., f.o.b. Baltimore	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina	net ton	5.00	—	7.50
Shellac, orange fine	lb.	.68	—	.70
Shellac, orange superfine	lb.	.78	—	.80
Shellac, A. C. garnet	lb.	.58	—	.60
Shellac, T. N.	lb.	.68	—	.70
Soapstone	ton	12.00	—	15.00
Sodium chloride	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars	ton	7.50	—	11.00
Talc, imported	ton	30.00	—	40.00
Talc, California talcum powder grade	ton	18.00	—	25.00

Refractories

Financial, Construction and Manufacturers' News

Construction and Operation

California

OAKLAND—The American Petroleum Co., 343 Sansom St., San Francisco, has awarded a contract to Hannah Bros., 142 Sansom St., for the erection of a 2-story plant on the waterfront at Oakland, estimated to cost close to \$25,000. Carl Werner, Humboldt Bank Bldg., San Francisco, is architect.

LOS ANGELES—Fire, Nov. 4, destroyed a portion of the plant of the Elaterite Co., manufacturer of rubber composition products, entailing a loss which is estimated at about \$85,000.

OAKLAND—The National Lead Co., 485 California St., San Francisco, Cal., has awarded a contract to the Cahill-Vensano Co., 110 Suter St., for the erection of a 3-story plant at East 10th St. and 41st Ave., Oakland, to cost \$49,000.

Connecticut

PLAINVILLE—The Plainville Castings Co. has awarded a contract to the Torrington Building Co., Torrington, Conn., for the erection of a 1-story brick addition, 62 x 160 ft.

BRIDGEPORT—The Crane Co., manufacturer of steam specialties, metal products, etc., is taking bids and will soon award contract for the erection of a 1-story addition to its local plant on South Ave. It will be 75 ft. x 175 ft., and will be used for the most part as an annealing works. The installation will comprise 10 new annealing furnaces, oil-fired, with auxiliary operating equipment.

Florida

FERNANDINA—The Florida Terminal Co. is perfecting plans for the erection of a new analytical chemical laboratory for phosphate and other analysis. It will be equipped with crushing machinery, pulverizing machinery, and general operating apparatus. Ernest Molnar is chemist for the company; R. M. Martin is plan superintendent.

Illinois

ELGIN—The Woodruff & Edwards Co., manufacturer of metal castings, etc., has awarded a contract to the Illinois Hydraulic Stone & Construction Co., 24 South 21st St., for the erection of a new 1-story foundry addition, 50 x 100 ft., to cost about \$15,000.

CHICAGO—The Diamond Red Paint Co., 2750 North Lincoln St., is taking bids for the erection of a 1-story side addition at its plant, 30 x 80 ft. Frederick C. Teich, 305 South La Salle St., is architect.

Louisiana

GRETNA—The United States Flour Milling Co., Kansas City, Mo., is planning for the construction of a new branch plant at Gretna. Work will be commenced at an early date.

Maryland

BALTIMORE—The American Oil Co., American Bldg., is considering the construction of a new 1- and 2-story building on Haines St., 130 x 300 ft., estimated to cost in excess of \$250,000.

BALTIMORE—The Chesapeake Paper Board Co., Key Highway, is perfecting details for enlargements in its plant to increase the output from 50,000 to 100,000 lb. of paper board products per day. Considerable new machinery will be installed, estimated to cost close to \$50,000. A new power house will be constructed. J. S. Smith is president.

BALTIMORE—Richard K. Meade & Co., 11 East Fayette St., engineers, have plans well under way for the proposed lime plant to be erected at the paper and pulp mills of the Bathrust Co., Ltd., Bathrust, New Brunswick, N. S. The plant will include two large kilns, provided with automatic stokers and operating under induced draft. A platform elevator for limestone handling will be installed.

Massachusetts

BOSTON—The Revere Sugar Refinery, 327-53 Medford St., has filed plans for the erection of a 1-story melter plant addition at its works.

BOSTON—The Eastern Salt Co., care of Shepard & Stearns, 65 Franklin St., architects, has awarded a contract to the Scully Co., 118 First St., Cambridge, Mass., for the erection of a new 1-story building.

ARLINGTON—The Frost Insecticide Co., 20 Mill St., has awarded a contract to the Holt-Fairchild Co., 248 Boylston St., Boston, for the erection of a 1-story building at its plant, 45 x 100 ft., to cost about \$40,000. Work will be placed under way at once.

Michigan

MOUNT PLEASANT—The National Portland Cement Co., 516 Book Bldg., Detroit, will defer the erection of its proposed new 2-story cement mill on Coldwater Lake, near Mount Pleasant, until early in the coming year. Preliminary plans are being drawn. The plant is estimated to cost close to \$500,000, including machinery. H. C. Shields is manager.

PORT HURON—The Port Huron Sulphite & Paper Co. will commence the immediate construction of additions to its paper mill to cost in the neighborhood of \$750,000 with machinery.

ST. JOSEPH—The Industrial Rubber Co. is said to be planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated at \$65,000.

OTSEGO—The Mac Sim Bar Paper Co. will call for bids before the close of the month for the construction of its proposed new 1-story power plant for paper mill service, 85 x 140 ft., estimated to cost about \$300,000 with machinery. Billingham & Cobb, Press Bldg., Kalamazoo, Mich., are architects. A. B. Thomas is president and general manager.

CHEBOYGAN—The Cheboygan Tile & Roofing Co. has commenced production at its new local plant and plans for extensive operations. The plant will be devoted to the manufacture of brick and tile products, and it is proposed to develop an output of about 30,000 bricks and tiles per day. The company has secured large clay properties in this section.

Minnesota

MANKATO—The Carney Cement Co. will defer further work on the construction of additions to its local mills, foundations for which recently have been laid. A total of eight buildings will be erected, and plans for the superstructures have been drawn. It is expected to proceed with the expansion as soon as conditions in the industry warrant. Richard K. Meade & Co., 11 East Fayette St., Baltimore, Md., are engineers.

Montana

MILES CITY—The Miles City Refining Co. has preliminary plans under way for the construction of a new oil refinery to cost about \$40,000. R. H. Daniels is secretary.

New Jersey

LINDEN—The Warner-Quinlan Co., 79 Wall St., New York, has commissioned George Gifford, engineer, 227 Fulton St., New York, to prepare plans for the rebuilding of its asphalt refining plant at Linden, recently destroyed by fire with loss estimated at close to \$2,000,000, including tanks, stills, manufacturing and mechanical buildings, power plant, etc. W. W. McFarland is general manager.

New York

NEW YORK—Goldberger Bros., 842 Third Ave., manufacturers of plate glass, have leased the 5-story building at 27th St. and First Ave., on site 74 x 95 ft., comprising about 30,000 sq. ft. of floor area, for a new works.

OGDENSBURG—The Bob White Chemical Co., 39 Broadway, New York, has completed plans for extensions and improvements in its plant at Ogdensburg, 1-story and basement, 80 x 145 ft., to cost about

\$25,000. The work will include laboratory enlargement. W. T. Smith is vice-president.

Ohio

WOOSTER—The Wooster Rubber Co. has preliminary plans under way for the erection of a 2-story plant, 40 x 85 ft.

Oklahoma

OKMULGEE—The Interstate Glass Co. is considering the erection of a new plant to cost about \$100,000, including machinery. H. J. Walter is president.

Pennsylvania

SCRANTON—The Diamond Oil & Paint Co., 211-19 South Seventh Ave., has awarded a contract to the R. D. Richardson Construction Co., Connell Bldg., for the erection of its proposed 2-story building on Seventh Ave., estimated to cost close to \$60,000. Edward J. Lynott is president.

ERIE—The Keystone Rubber Mfg. Co., 1413 East 11th St., has commenced the rebuilding of its plant destroyed by fire several months ago. It will be 3-story, 65 x 125 ft., located at 11th and French Sts. A. W. Tuttle, 618 East Seventeenth Ave., is the building contractor. Joseph B. Mooney is president.

SHARON—The Carnegie Steel Co., Pittsburgh, has commenced the dismantling of its local plant, comprising 6 basic open-hearth furnaces, heating furnaces, blooming and finishing mills. The blast furnace at the site will be left intact. The plant has been closed since May 1st of last year and under normal operations gave employment to about 700 men. The equipment will be used by the company at its other works.

Rhode Island

PROVIDENCE—The Charles S. Tanner Co., 250 South Water St., manufacturer of starch, etc., will break ground at once for the erection of its new 2-story plant, 50 x 76 ft., at South Water and Coin Sts.

Tennessee

CHATTANOOGA—The Southern Cotton & Paper Co. has plans under way for the erection of a 1-story plant, 50 x 160 ft., on site recently acquired, totalling about 2 acres of land. The mill will be equipped to specialize in the manufacture of bond and other papers from cotton linters, with initial daily output of about 15 tons. Mercer Reynolds heads the company.

Texas

ROCKDALE—G. C. Holmes & Co., Houston, have presented a proposition to the local Chamber of Commerce for the erection of an oil-refining plant, the cost to be equally divided between the two interests.

Washington

SPOKANE—The Consolidated Diamond Oil & Refining Co., with temporary offices in the Spokane Hotel, is arranging for the early construction of a new refinery on property acquired at Dishman, near Spokane.

SEATTLE—The Washington Cord Tire Co. has acquired a site totalling about 10 acres of land at Vancouver, Wash., for the erection of a new plant for the manufacture of automobile tires and other rubber products. F. C. Plouf is president.

West Virginia

RICHWOOD—The Cherry River Paper Co. has broken ground for the erection of a 1-story and basement power plant for general paper mill service, 40 x 150 ft., estimated to cost in excess of \$250,000. George Snyder is assistant superintendent.

Wisconsin

MILWAUKEE—The American Hide & Leather Co., 14th St., is having plans prepared by Lockwood, Greene & Co., 38 South Dearborn St., Chicago, Ill., engineers, for the rebuilding of its local tannery on Commerce St., recently destroyed by fire with loss in excess of \$200,000.

Weightman & Steigley, 3420 Parker Ave., Chicago, are preparing plans for a group of buildings for a canning factory in northern Wisconsin to cost a total of \$250,000. The buildings include a 2-story building, 96 x 48; a 1-story building 36 x 38; a 1-story building 60 x 60, one boiler house 32 x 32 to contain high pressure boiler for process steam for cooking purposes. Other buildings will include a two-section warehouse, each section 96 x 48, two stories in height, and one reinforced-concrete antiseptic tank. The architects are receiving bids for these structures, as well as the apparatus to be used in the process.

New Companies

THE PRODUCERS PAPER Co., 208 South La Salle St., Chicago, Ill., has been incorporated with a capital of \$32,000, to manufacture paper products. The incorporators are Robert J. Magill, R. W. and Herbert S. Nock.

THE GENERAL GALVANIZING CORP., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture galvanized metal products. The incorporators are A. Ross, C. and L. Pervitali. The company is represented by Henry Gerson, 30 East 42d St.

THE KEAN LEATHER Co., Woburn, Mass., has been incorporated with a capital of \$50,000, to manufacture leather products. Carl R. Bedell is president; and Frederick C. Kean, 40 Arlington Rd., Woburn, treasurer.

THE CALIFORNIA-CAROLINA OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000, to manufacture petroleum products. The incorporators are J. L. Bird, W. A. Love, and Carlisle Williams. The company is represented by W. and L. M. Chapman, 1015 Citizens' National Bank Bldg., Los Angeles.

THE HABERLAND MFG. Co., Jersey City, N. J., has been incorporated with a capital of \$1,200,000, to manufacture chemicals and chemical byproducts. The incorporators are Paul Haberland, William H. Fain and Paul C. Whipp. The company is represented by the United States Corporation Co., 15 Exchange Pl., Jersey City.

THE TUCKER WATERPROOFING & INSULATING Co., Brockton, Mass., has been incorporated with a capital of \$95,000, to manufacture insulation specialties, waterproofing products, etc. William R. Tucker is president; and George Tucker, Brockton, treasurer.

THE ILLMO OIL Co., Murphy Bldg., East St. Louis, Ill., has been incorporated with a capital of \$25,000, to manufacture oil products. The incorporators are Edward C. and William F. Friedewald, and Thomas B. Edwards.

THE STAR DUST PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture composition mineral products. The incorporators are J. Andrews, Jr., D. Worth and E. Freeman. The company is represented by Pease & Mason, 120 Broadway, New York.

THE CHEMICAL OIL REFINING Co., Wilmington, Del., has been incorporated under state laws with capital of \$300,000, to manufacture refined oil products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE AMERICAN PRODUCTS Co., Jacksonville, Fla., has been incorporated with a capital of \$1,000,000, to manufacture chemicals and chemical byproducts. B. F. Williamson is president, and J. T. McCarthy, vice-president, both of Gainesville, Fla.

THE NOTTINGHAM RUBBER Co., Trenton, N. J., has been incorporated with a capital of \$500,000, to manufacture rubber products. The incorporators are Samuel H. Bell, I. Alexander and C. Francis Fisk, 150 East State St., Trenton.

THE NORTHERN PENNSYLVANIA CHEMICAL Co., Coudersport, Pa., has been incorporated under Delaware laws with capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are E. P. Huntingdon and J. T. Mansfield, Coudersport; and Frederick Walker, Knoxville, Pa. The company is represented by the Capital Trust Co., Dover, Del.

THE HATHAWAY OIL Co., New Bedford, Mass., has been incorporated with a capital of \$30,000, to manufacture oil products. John M. Hathaway is president, and R. Eugene Ashley, New Bedford, treasurer.

THE TRUAMAN FERTILIZER Co., Jacksonville, Fla., has been incorporated with a capital of \$200,000, to manufacture fertilizer products. R. B. Trueman is president; J. J. McGrath, vice-president; and G. R. Needham, secretary-treasurer, all of Jacksonville.

THE BRAENDER RUBBER & TIRE Co., Wilmington, Del., has been incorporated under state laws with capital of \$1,100,000, to manufacture automobile tires and other rubber products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE SUSH LEATHER Co., New York, N. Y., has been incorporated with a capital of \$16,000, to manufacture leather products. The incorporators are S. S. Sush, I. Levin and J. E. Rivlin. The company is represented by Harry Levin, 132 Nassau St., New York.

THE DAVIS CHEMICAL Co., 12 West Park St., Providence, R. I., has filed notice of

organization to manufacture chemical products. George D. Mitchell heads the company.

THE AMERICAN MICA MINING Co., Newport News, Va., has been incorporated with a capital of \$250,000, to operate mica properties and manufacture mica products. Allan D. Jones, Newport News, is president; and H. C. Field, Axton, Va., secretary.

THE BLACK SEAL LUBRICANT Co., INC., 1305 Maryland Ave., Baltimore, Md., has been incorporated with a capital of \$100,000, to manufacture oils, greases and other lubricants. The incorporators are James G. Paugh, Frank H. Kelley and Peter Peck.

THE KALCO PRODUCTS Co., INC., New Haven, Conn., has been incorporated with a capital of \$10,000, to manufacture alkalis, chemicals and affiliated products. The incorporators are David Kaltman, Henry Zatulove and S. A. Skiff, 19 Congress Ave., New Haven.

THE ROSS LABORATORIES, INC., Philadelphia, Pa., has been incorporated with a capital of \$100,000, to manufacture chemicals, dyestuffs, colors and affiliated products. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia.

New Publications

"HANDLING LIQUID CHLORINE" is the title of a four-page leaflet containing D. K. Bartlett's paper read before the National Safety Council Congress at Boston, Sept. 28, 1921.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circular 8, Testing of Thermometers; Circular 114, Standard Specifications for Cotton Rubber-Lined Fire Hose; Sci. Paper 410, Thermal Expansion of Copper and Some of Its Important Industrial Alloys, by Peter Hidnert; Sci. Paper No. 413, A Portable Vacuum Thermopile, by W. W. Coblentz; Sci. Paper 414, Interference Measurements in the Spectra of Argon, Krypton and Xenon, by W. F. Meggers; Sci. Paper 416, Preparation of Galactose, by E. P. Clark; Tech. Paper 190, "Black Nickel" Plating Solutions, by George B. Hogaboom, T. F. Slattery and L. B. Ham; Tech. Paper 191, Some Factors Affecting the Life of Machine-Gun Barrels, by W. W. Sveshnikoff; Tech. Paper 192, Tests of Centrifugally Cast Steel, by George K. Burgess; Tech. Paper 195, Zinc Cyanide Plating Solutions, by William Blum, F. J. Liscomb and C. M. Carson.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 186, Investigations of Zirconium, With Especial Reference to the Metal and Oxide. Historical Review and Bibliography, by J. W. Marden and M. N. Rich; Bull. 206, Petroleum Laws of All America, by J. W. Thompson; Tech. Paper 261, Oil-Camp Sanitation, by C. P. Bowie.

THE COLORADO SCIENTIFIC SOCIETY, Denver, Col., has issued booklets on "Aspects of Colorado's Oil Shale Industry," by Arthur J. Hoskins, and "The Manufacture of Lubricating Products From Wyoming and Colorado Crude Oils," by L. C. Welch.

THE MILWAUKEE ASSOCIATION OF COMMERCE has just issued vol. 1 under date of August, 1921, of *Milwaukee*, a magazine for business leaders. C. B. Traver is editor and K. H. MacArthur business manager. Editorial contents are devoted to the forwarding of local industries.

BAYLEY MFG. Co., of Milwaukee, Wis., has issued a new folder on the Bayley Thermo-unit for heating and ventilating. This device is a new one and peculiarly adaptable for heating dye houses and small industrial buildings of all kinds. It is a complete indirect heating system with a heating surface consisting of individual spiral radiators, so valved that one or more coils may be cut out as temperature variations demand. The fan takes the air from the floor line, forces it through the heating coils into the room at about 6 ft. above the floor and returns it to the coils as it cools, thus forming a continuous cycle as long as heating is required. If desired, all or part of the air can be taken from the outside, thus combining ventilation with indirect heating.

THE UNIVERSITY OF MONTANA has issued a bulletin on "Geology and Oil and Gas Prospects of Central and Eastern Montana," by C. H. Clapp, Arthur Bevan and G. S. Lambert.

THE STATE OF LOUISIANA, DEPARTMENT OF CONSERVATION, has issued Bull. 9, on "The Monroe Gas Field," by H. W. Bell and R. A. Cattell, petroleum engineers of the U. S. Bureau of Mines.

"THE USE OF POWDERED FUEL UNDER STEAM BOILERS" is the title of a pamphlet recently published by the Combustion Engineering Corp., N. Y.

Capital Increases, Etc.

THE MERLIN KEILHOLZ PAPER Co., 296 Broadway, New York, N. Y., has filed notice of increase in capital from \$150,000 to \$250,000.

THE MUTUAL OIL Co., Adrian, Mich., has filed notice of increase in capital from \$45,000 to \$100,000.

THE IROQUOIS FOUNDRIES, INC., Utica, N. Y., has filed notice of dissolution under state laws.

THE DOVAN CHEMICAL Co., a Delaware corporation, has filed notice of intention to operate in New Jersey for the manufacture of chemical products. Kenneth A. Christian, 441 Riverside Ave., Newark, N. J., represents the company.

THE MAYWALD RUBBER Co., Nutley, N. J., manufacturer of rubber products, has arranged for the sale of a preferred stock issue, the entire distribution to total \$250,000. The proceeds will be used for expansion. Frederick J. Maywald is president, and George C. Plummer, vice-president and treasurer.

THE OLYMPIC CHEMICAL Co., 954 Leggett Ave., New York, N. Y., has filed notice of increase in capital to \$20,000.

THE BRADSTREET OIL Co., Tulsa, Okla., has filed notice of increase in capital from \$200,000 to \$1,000,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1921. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Emerson Hotel.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1921.

AMERICAN PETROLEUM INSTITUTE will hold its second annual meeting at the Congress Hotel, Chicago, Dec. 6, 7 and 8.

COLLEGE OF THE CITY OF NEW YORK, department of chemistry, will give public lectures under the auspices of the City College Chemical Society in the Doremus Lecture Theater, at 4:30 p.m., as follows: Nov. 30, "Afterthoughts of the War," by Leland L. Summers, of the War Industries Board; Dec. 6, "America in Chemistry," by Dr. Edgar F. Smith, provost emeritus, University of Pennsylvania, and president, American Chemical Society.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting; Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Can Mild Steel Have

750,000 Lb. Ultimate Strength?

SOMETIMES theoretical reasoning leads to results of peculiarly "practical" significance. As an instance, in a recent number of the *Philosophical Transactions* of the Royal Society of London, A. A. GRIFFITH presented a study of "The Phenomena of Rupture and Flow in Solids," giving especial attention to the influence of cracks. Mathematical studies of the problem of elasticity are complex enough, one would think, without complicating the matter by analyzing the stresses in a cracked plate, and the results expressed in double integrations and partial differentiations are absolutely unintelligible to almost all engineers. Fortunately, however, Mr. GRIFFITH, who is an engineer himself, interpreted his algebraic results into understandable words, and then commented upon their application to phenomena observed every day, but about which we really know very little.

His mathematics indicated that fatigue strength should be nearly independent of the depth of surface scratches. That is to say, a sharp bottomed scratch 0.0001 in. deep left by finest emery cloth should weaken a specimen about as much as a visible scratch of the same shape, a conclusion evidently at variance with carefully executed tests. Considering this discrepancy from many viewpoints, the author holds fast to the theoretical deduction that rupture in an isotropic elastic material always occurs at a certain maximum tension. In the limit, the maximum strength would be given by a single string of molecules, and should be from 1,000,000 to 1,500,000 lb. per square inch for hard glass. As a matter of fact such glass has an ultimate strength of 24,900 lb. per square inch when tested in small rods.

Here is a variation between theory and practice which would doubtless excuse the conservative and unimaginative from remarking, "That's about as close to the ground as those theoretical chaps ever get!" But it only urged GRIFFITH and his friends to redouble their efforts to bring the two into agreement. In fact, it was not long before he was able to prepare thinner and thinner filaments of this same glass bearing greater and greater and greater loads, until finally the perfectly amazing strength of 491,000 lb. per square inch was attained in a hair 0.0012 in. in diameter! Extrapolating to molecular dimensions, the maximum strength was estimated to be 1,600,000 lb. per square inch, a result which agrees with their theoretical deduction fairly well, considering the fact that one estimate was extrapolated and the other computed by the aid of approximate figures for surface tension of solid glass at room temperature.

A plausible reason for the comparative weakness of ordinary test specimens is that the usual tests impose stresses which are far from uniform, and that the non-uniformity of stress is similar to that set up

were a supposedly homogeneous material full of minute flaws. Mathematical analysis again shows that these flaws should be relatively large as compared to molecules, having a width of the order of ten thousand times the molecular distances.

The nature of these "flaws" is somewhat speculative, since this size is large enough to be seen under a good microscope. At any rate, the author remarks that "the effective strength of technical materials might be increased ten to twenty times at least if these flaws could be eliminated." Perhaps Mr. GRIFFITH would regard the strengthening of metal by cold work—most commonly observed in high strength wires—as a suppression of flaws in metals; a conclusion somewhat at variance with accepted ideas as to the nature of cold work. Even so, his experimental results on glass filaments show that his theoretical deductions are within reason and his suggestions worthy of careful consideration. Soft iron having a strength of 750,000 lb. per square inch is a goal for the ambitious.

Canada and

The Tariff

THE story is told of a body of Northern Indians that set out once upon a time on a long mush, resolved to follow the North Star until they came to the end of the world. So they marched and marched until finally they reached a great open place where there was nothing but ice and snow, where there were neither trees nor vegetation that they could see or use for tepees or where game might abound. It was a frozen desert where no man could live, and so it must be the end of the world. Then they turned back toward the south again.

There was also a troop of adventurous Esquimaux who likewise sought the end of the earth, and they set out to go as far as man could travel with the North Star directly back of them. And they went on and on until at last, after many weeks, they came to a place where the land was all covered with trees; where they could find no open plains and there was not snow enough to build an igloo for human habitation. It was a desert of woods and vegetation; there were neither seals nor polar bears nor any source of blubber. It was surely the end of the world, and so they turned back to the north again.

We like the story because the scene and *dramatis personæ* are suggestive of the United States and our friendly neighbor Canada. And we can imagine the Indians and Esquimaux crossing the international boundary in their search, that boundary which has been happily referred to as a "thin, invisible border which is not a line of division so much as one that shows where the United States and Canada are united." We like the idea. If Canada were in Siberia, we should not be united; as it is we are. We move backward and forward across the line without think-

ing of each other as foreigners. We speak the same language, even the same accent; we intermarry; have family reunions and family squabbles, and whatever custom or habit establishes itself in one place is likely to be adopted in the other.

We haven't the same government and we don't want it, for each country has all that it can handle in managing its own affairs. What they would do with some of our Texas and Oklahoma Congressmen in Ottawa or what we should do with some of their French Canadian Deputies in Washington are, thank GOD, problems that do not call for solution. But when the Great Northern Railway needed to be developed there came JAMES J. HILL from Canada, and he did it. When they wanted ideals of life and duty depicted on the walls of the House of Parliament at Winnipeg they came to New York and got AUGUSTUS V. TACK to do it, and there they are, supreme in their loveliness and nobility. Were these things done because HILL was born in Canada and TACK in Pittsburgh? Not for a minute!

They have lots of coal in Canada, but it isn't developed, and they need coal from here. We need lumber and wood pulp and nickel and cobalt and lots of other things from there. We have had general discussions about free trade between the two countries, but they grew rather nasty and somewhat cantankerous, so we learned from that that we are not ready for it in this generation. Let's pass it by. But when it comes to writing a tariff bill it behooves us to bear in mind that we are dealing with our nearest neighbor, and that we have neighborly obligations. If the Great War has not taught us that obligations count in great affairs as well as in personal behavior, then indeed do the poppies bloom in vain on the fields of Flanders.

The Hon. JOSEPH W. FORDNEY is chairman of the Ways and Means Committee of the present House of Representatives and author of the so-called Fordney tariff bill. As it stands it is probably a dead issue; but some kind of a statute must be passed in the next session, and we think it fair to state that the proposed measure is neglectful of our neighborly obligations to Canada. Mr. FORDNEY lives in Saginaw, Mich., and is a considerable owner of timber lands. Over the border, in Canada, other persons own timber lands, and this Canadian lumber reduces Mr. FORDNEY's profits, which he does not like. We shall not discuss the relation of Canadian lumber to the rest of us; we are not considering our own welfare; we are trying to be sympathetic with Mr. FORDNEY. Canadian lumber is a real trouble to him, just as anything that stands in the way of our own profits is a trouble to us. Now these habitual troubles establish something like grooves in the mind, and we think through them, time and again, often unconsciously.

We do not say this in criticism of Mr. FORDNEY in general. Like the rest of us, he has his faults and his prejudices. But we urge upon Congressmen to bear this disposition of the chairman of the Ways and Means Committee in mind when the tariff bill comes up for discussion again; to remember that Canada is our nearest neighbor and that we have just as many obligations as we have rights and privileges; that we have the same borders, and very much the same kinds of trouble; that we are the same kind of people, and that we cannot strike Canada without hitting ourselves. We need each other.

A Misleading

Advertisement

IN THE current number of a leading textile journal we read the following advertisement: "Tell the truth! American chemists and manufacturers are entirely competent to shape their own destiny if afforded proper support and encouragement, without building a Chinese wall around themselves. Why becloud the issues and delude the public with threadbare 'war-talk' and similar bunk? Straight-thinking Americans are not afraid of 'ghosts' no matter from what country they come." Then follows advertising matter as to dyes for sale, and the signature is that of H. A. Metz & Co., Inc.

At the Farbwerke vorm, Meister Lucius und Brüning, at Hoechst, the company Mr. METZ represents can produce dyes at from one-third to one-half the cost of the same dyes made here. Their salaries and wages are one-sixth to one-seventh of those paid in the United States. They have large stocks of dyes and chemicals on hand ready for shipment to the United States against the lifting of the embargo. The Hoechst establishment is part of the Interessen Gemeinschaft, and despite the sore straits of the German Government and people, this great trust and its branch at Hoechst are reputed to be rich; they are reputed to have made vast quantities of high explosives and poison gases for the German army during the war and to have been paid for it. Suppose the "proper support and encouragement" which Brother METZ—for whose immense ability and shrewdness we have profound respect and whom we cannot help liking even though to our minds he is engaged in an effort that, if successful, will utterly destroy the synthetic organic chemical industry in the United States—suppose "encouragement" to the tune of 100 per cent or over 200 per cent duties were levied on German dyes, what would he and his partners do? They know the American dye and chemical markets as well as anybody else alive. Would they not underbid and underbid and get that trade at any cost for at least a year, until American competition was killed? Then wouldn't they and the Badische and Bayer and other people have it right in their own hands?

Brother METZ is an American, born here in New York, and we are willing to admit for his benefit all the loyalty he claims. But how about his friends over in Germany? We don't trust them. While HERMAN would be trying to save American industry, they would overrule him, we are sure; and he does not control the I. G. or even the Farbwerke Hoechst. It is the people back of him that we have reason to fear, and we reason from experience.

Now let's "tell the truth" again. American chemists and business men are not so competent that they can get away with costs of three or two to one against the Germans. American chemists have yet a great deal to learn with only five years' experience against the Germans' fifty. And as for the American manufacturers who are in the business they have still more to learn. In fact, if we only had HERMAN on our side with all his heart and all his interest, instead of representing interests that want to "serve" both German and American industries in that fine German brotherly fashion whereby the advantage and proceeds all go to Germany, we should feel better.

Suppose the Interessen Gemeinschaft gets into the saddle; gets control just as German manufacturers

once had control, then Brother METZ will fight in vain for his American customers. We know those Germans and we do not trust them as he does.

The only way to avoid German control is to do just as England and France and Italy and Japan have done: to put on an embargo and get what we need from Germany under license. That not only saves the industry here and keeps our chemists at work, but gives us also a complete arsenal of defense for chemical warfare in case Germany or any other country should get obstreperous again. And it will cut down our war taxes.

Underdevelopment

And Overdevelopment

BEFORE the war when there was an industrial depression the cry always was that the country was "overdeveloped." The development was all right in its way, but it had gone too far and it would require a period of time for people to catch up and require all the facilities that had been provided. Now we have a sort of industrial depression—at least nearly everyone claims there is one—and we do not hear the old familiar cry. Rather everyone is telling everyone that the country needs a great deal of developing, that it is far behind in its "program." Curious, isn't it?

The one thing common to all the times is the disposition to pick out something to blame it on. That is human nature. No one is disposed to indulge in introspection and confess his own faults when found. Some of the claims made as to what is wrong just now will not bear analysis, but it is not customary to analyze things that are said by everybody, although they are usually the things one should be wary of.

The difficulty arises largely from a loose method of thinking, a disposition to regard "development" as something that necessarily proceeds along fixed lines, so that we must be either underdeveloped or overdeveloped or developed just right. Nobody ever admits that things are just right! Obviously, however, development is of various kinds, and styles or demand may change. We may have gone too far in one direction and not far enough in another.

There can scarcely be overproduction of everything that men want, for the average man is willing to spend his income, but there may easily be an excess of capacity for making things that men do not want a great deal, and a lack of capacity to produce things men would like to have once they knew of their existence. It does not follow that because our rate of producing a given thing, whether portable property or fixed property, used to increase at a certain rate, perhaps by a geometrical progression, it should continue to do so until doomsday. Fourteen years and more ago we were building steel freight cars at the rate of 150,000 to 250,000 a year, but it does not follow that we need to build them at that rate throughout the future. A third of a century ago there was a year in which we built 13,000 miles of railroad, but we do not have to do that now. Often in the past the production of coal doubled in less than a decade, and it more than doubled in the 16 years from 1902 to 1918, but we certainly do not have to keep up that particular sort of thing indefinitely.

In 1873 there began the severest industrial depression in the history of the United States. The country was "overdeveloped," of course. Then somebody brought roller skates to the attention of the public,

and old timers insist that the building of roller-skating rinks all over the country did much to curtail unemployment. The country was overdeveloped in methods and means to get from one city to another, but underdeveloped in means for skating around a circle. Nowadays there is a vast amount of money being spent in admissions to "movie" shows by people who simply refuse to buy steel beams and channels.

We are going to keep on developing, but not necessarily along the same lines as formerly. We need some new highways to be marked out and as they are marked out men will travel them. A couple of decades hence it will look very simple in the retrospect. We shall not have built 4,000,000 or even 2,000,000 freight cars in the 20 years, or laid 100,000 miles of new railroad or doubled our production of coal or quadrupled the number of skyscrapers or provided one automobile per capita—but we shall have made a great deal of progress, chiefly along new lines, making life more interesting.

The Banker

And Research

"OUR industry will spend any amount for lawyers, but almost nothing for chemists." This was the complaint of a very prominent technical man who has striven tirelessly for several years past to "sell" his industry the idea of the importance of fundamental research. He has frequently had the experience that any threatened attack upon that industry, which happens to be one very much in the public eye, will promptly bring any necessary sums for co-operative effort in a legal or economic contest to prevent successful inroads upon the industry's interests. However, just recently one prominent corporation in this industry experienced great difficulty because of unsuspected poisoning of a large number of plant employees. It was obvious to any technical observer that a careful study of the characteristics of the vapors coming from the process would undoubtedly give the cause and probably suggest a remedy for this danger. Nevertheless it proved almost impossible to get the small appropriation needed for this study despite the fact that neglect of the situation promised to result in serious consequences to workmen and damage claims far in excess of the amount needed for the research.

Altogether too many misunderstandings exist between business on the one hand and science and educational institutions training scientists on the other. This misunderstanding is simply the result of radical difference in point of view, a difference for which both parties are about equally to blame. Science has taken too little pains to find out just what industry by and large needs and can use and has all too often taken the stand that results should in themselves be accepted and appreciated at their face value. Neither of these stands can be justified.

On the other hand, industry has been, and still often is, to blame for its unwillingness to use that which is of real value in science. Practically every industry is based upon scientific methods and can advance only as new knowledge can be applied in industrial operations. The last word in business management generally is spoken by the banker. It is a doubly welcome event, therefore, which shows that the banking interests are more and more appreciating chemical science in its fundamentals. It is to be hoped that the science will be increasingly deserving of such appreciation.

Readers' Views and Comments

Boiler Feed Water Purification

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a letter which appeared in your issue of Oct. 5, 1921, William M. Taylor criticizes an article by the writer on "Boiler Feed Water Purification." In brief he makes the following assertions:

(1) Zeolite softeners do not produce water of zero hardness and by the very nature of the chemical reactions involved are not capable of producing water of zero hardness.

(2) Sodium salts in the raw water in slight amount prevent the complete softening of the water.

(3) The molecular weight of the sodium salts in the zeolite softened water exceeds the molecular weight of the calcium and magnesium salts present in the raw water by about 68 per cent instead of only 5 per cent, which the writer sets forth in his article.

The assertions are not in accordance with the facts for the following reasons:

(1) Any chemist can very quickly and easily prove that a zeolite softener, if properly operated and constructed, will soften water to absolute zero hardness, as defined in the "Standard Methods for the Examination of Water and Sewage."

Mr. Taylor claims to have analyzed the effluent from various zeolite softeners, and found slight amounts of hardness up to about 0.5 grain per gallon, expressed as calcium carbonate. But he does not mention that he examined the conditions under which the said softeners were assumed to be operating, and whether the operation was being cared for properly. The general statement that he did not find a water of "zero hardness," without giving further pertinent details of the operating conditions, does not prove anything. It would be just as logical to claim that an engine or turbine could not possibly meet the manufacturers' guarantee for economy because in some particular test, without checking up operating conditions, it did not do so.

(2) The amount of sodium salts in the raw water has an influence on the capacity of the softener—that is, the amount of "zero hardness" water produced—but it does not prevent the production of "zero hardness" water. The softener should be designed properly with a sufficiently greater excess of the zeolite to take care of such conditions. This is in accordance with the law of mass action of most reactions. But Mr. Taylor has exaggerated this inhibitive tendency of sodium salts in the raw water. Zeolite plants have successfully handled waters containing over 1,000 parts per million of sodium chloride.

(3) Regarding the relative molecular weights of the sodium salts in the softened water and the weights of calcium and magnesium salts in the raw water, Mr. Taylor states, "His chemical arithmetic is not accurate," and then proceeds to fall into an inexcusable error. He compares calcium carbonate on one side of the reaction with sodium bicarbonate on the other side. According to Mr. Taylor's comparison a reaction must be assumed analogous to the following formula. Thus:

A glance at the formula shows that it is not an equa-

tion and does not balance. There is an extra CO_2 and H_2O on the right side which are not on the left.

The correct equation is:

Now, 168 is only 6 more than 162, which is $6 \div 162 = 3.7$ per cent excess.

This is less than 5 per cent, which was the figure stated by the writer in the original article, and it is certainly not 68 per cent, which Mr. Taylor claims.

Mr. Taylor mentions that " CaCO_3 is held in solution by half-bound CO_2 " but then does not apply the idea in the calculation. Hardness is frequently expressed in terms of CaCO_3 for convenience, but CaCO_3 , as such, is relatively insoluble in water, and it is only when the water contains CO_2 that CaCO_3 is dissolved in the form of $\text{Ca}(\text{HCO}_3)_2$. That is how limestone is dissolved and how this form of hardness enters our natural water supplies.

Assistant Technical Manager.

Communications With Russian Scientists

To the Editor of Chemical & Metallurgical Engineering

Sir:—I have read with great interest and appreciation your editorials concerning Russian scientists in general and my professor Ipatieff in particular.

Prof. Ipatieff is a graduate of Michael Artillery School and later of Michael Artillery Academy. Several years before the last war he attained the rank of general in the Russian artillery. He held the chair of professor in organic chemistry in Michael Academy and at the same time delivered lectures in Michael Artillery School and in the University of Petrograd.

So far as I know he continued his work during the period of the revolution and, as I understand it, he even published some of his works in the recent publications of the Russian Academy of Science.

I think that the best way to communicate with him as well as with other Russian scientists is in care of the Russian Academy of Science. Proper address would be as follows, both in English and Russian:

Russia, Petrograd,
c/o Academy of Science,
Professor Ipatieff.

Россія. Петроград.
Академія Наук.
Профессору Ипатьеву.

Mt. Rainier, Md.

COLONEL A. I. KRYNITZKY.

A Notable Movement in Metallurgical Education

To the Editor of Chemical & Metallurgical Engineering

Sir:—I have just read with much interest the editorial entitled "A Notable Movement in Metallurgical Education" that appears in the Nov. 6 issue of CHEMICAL & METALLURGICAL ENGINEERING. There is one exception that I have to make and that is in connection with my membership in the New Haven Chapter. New Haven has a very active and creditable chapter in the American Society for Steel Treating, but it is my good fortune to be a resident of Hartford and a member of the Hartford Chapter, which we believe ranks second to none in the Society.

Hartford, Conn.

F. P. GILLIGAN,
President, American Society for Steel Treating.

Italian Chemical Industries

From Our Special Correspondent

GENOA, Italy, Nov. 2, 1921.

STRIKES have occurred in the chemical industries during the past month, owing to the refusal of the workmen to accept the reduced scale of wages arranged for the winter months. The workmen contended that the cost of living had increased owing to the higher foreign exchange. This condition and the fact that the demand for chemicals on the part of consumers and speculators has increased would naturally lead to the expectation that prices would be higher, but such is not the case. The price of a few articles rose, but the great quantities of borax, camphor, ammonium carbonate, calcium chloride, magnesium chloride, cream of tartar, formaldehyde, acetone, caustic soda and the like coming in from Germany kept the price of these chemicals down. This has injured the export business from nations having a higher rate of exchange, such as the United States and Great Britain.

ITALIAN CITRIC ACID INDUSTRY

Because the government fixed the price of citrate of lime at 10,000 lire per ton, the Italian citric acid industry, with works at Palermo, Messina and Vercelli, is having a difficult time, being no longer in a position to produce the acid at a price to compete against tartaric acid, and has been obliged to reduce orders. Besides this, the industry found it difficult to sell citrate of lime at the new price to foreign works producing citric acid. The exportations of this product had risen in 1920 to 8,777 tons, 5,738 tons being destined to the United States, 1,634 tons to England, 746 tons to France and the remainder to Germany and other countries. The exportations during 1919 amounted to only 3,458 tons.

ITALIAN SUGAR PRODUCTION

Owing to favorable weather conditions and to the greater beet-root acreage cultivated, the production of sugar will be greatly increased this year, surpassing 200,000 tons; last year it was only 100,000 tons. The internal consumption, calculated at 220,000 tons, will therefore be nearly covered and the importations will be greatly reduced. These reached 66,160 tons during the first six months of this year. In 1918 there were thirty-four sugar works in Italy and the average yearly production was between 100,000 and 150,000 tons. The importance, therefore, of this year's increase can be realized.

ITALIAN SHALE DISTILLATION

So far very little has been accomplished in Italy in the distillation of bituminous or asphaltic rock to obtain mineral oil for combustible purposes. What little has been done has been limited to a single works, the Società Italiana Asfalti, Bitumi, Catrami e Derivati, which has constructed a plant for producing 15,000 tons of mineral oil per annum. After the success of this concern was assured, a number of Italian economists started a campaign to utilize the great abundance of asphaltic rock and lignite throughout continental Italy. It has been sought to interest the government in a plan for the protection of the new industry, but little is expected from this quarter, owing to the fact that the government is already

occupied with enough to keep it busy for some time. Neither is much to be expected from Italian capitalists, because of their present financial difficulties. It has been suggested that this would be a field worthy the attention of American financiers, taking advantage of the present low value of the Italian lire. It is contended that whereas now the shale deposits are powdered and exported for road-making purposes, they could with comparatively little expense be distilled in Italy. In 1920 Italy imported 182,004 tons of mineral oil, valued at 235,000,000 lire, most of which came from the United States, Mexico, Great Britain and France.

HYDRO-ELECTRIC DEVELOPMENTS

The electric substation of Predare started operation during October. This is the first of a group of hydro-electric power substations to be constructed by the Società dell'Ozola in the Reggio Appenines, and is also the first to distribute on a very large scale electric energy between different Italian regions. For the present it will transmit electric energy of the Società Adamello toward the Tuscan region, but later it will also include a hydro-electric power-generating station. The lines of the Società Adamello are already connected with those of the Società Edison, Società Conti and others, and will be connected during the next few months with the lines of the Società Adriatica, and later with plants in Piedmont. In this way will be formed a large inter-regional distribution of the electric energy produced in the power stations of the Nerina, Adamello and Aosta Valleys to points in all portions of northern and central Italy.

ITALIAN IMPORTS AND EXPORTS

The financial difficulties suffered in Italy by all classes and which were rendered more serious by the heavy taxes reduced all importations during the first six months of this year, as can be seen from the following figures:

	Jan.-June, 1921 Tons	Jan.-June, 1920 Tons
Chemicals	60,500	133,041
Acids	7,049	14,143
Paints and varnishes	3,942	6,454
Wood pulp	19,530	37,329
Malt	1,436	869
Petroleum	32,798	65,636
Cottonseed oil	11,254	9,288
Metallie minerals	15,099	15,052
Cast iron and steel scrap	20,832	90,290
Pig iron, cast iron and steel ingots.	35,678	96,028
Iron and steel (sheets, bars, wire)	107,121	126,048
Galvanized and lead covered steel and iron plates	10,338	22,163
Copper, brass and bronze	10,630	7,575

Despite the efforts of Italian producers to increase their exports, success could be attained in only some cases. This is demonstrated by the following export statistics, which are those available for the first six months of the present year:

	Jan.-June, 1921 Tons	Jan.-June, 1920 Tons
Chemicals	43,327	28,454
Acids	5,188	5,515
Paints and varnishes	1,521	1,204
Wood pulp	653	None
Metallie minerals	7,082	8,184

Heavy importations of war reparation coal permitted an increase of exportations of coal from this country, that reached 102,802 tons in the first six months of this year, against 36,582 in the corresponding months of last year. The importations of coal were reduced to 2,346,914 tons during the six months, against 2,594,612 in the corresponding months last year.

The Manufacture of Naval Stores From the Dead Wood of the Southern Pines

Recent Industrial Development of the Process for the Extraction of Turpentine, Rosin and Pine Oil From Stumps and Other Dead Wood of Cut-Over Pine Lands—Solvent Treatment and Recovery—Chemical and Physical Properties of Products

By C. M. SHERWOOD

Naval Stores Division, Hercules Powder Co.

THE extraction of rosin, pine oil and turpentine from dead pine wood is a comparatively recent process. The first plant was erected at Gulfport in 1909 by the Yaryan Naval Stores Co. and had a capacity of about 90 tons of wood per day; in 1911 this was increased to 175 tons. In 1912 the same company built an additional plant of a much greater capacity at Brunswick, Ga. Since that time several other installations have been made until at present there is a total of eight plants, ranging in capacity from 20 to 550 tons of wood per day.

In May, 1921, the Hercules Powder Co. assumed control of the Yaryan Rosin & Turpentine Co., a reorganization of the older company, and also about that time completed a plant at Hattiesburg, Miss. The combined maximum capacity of these plants is approximately 1,000 tons of wood per day, making this company the largest producer of naval stores by the extraction process in the world.

Up to the present time it cannot be said that this industry has been profitable. The Yaryan company was in receivers' hands during a large part of its existence and it would probable have been a total loss to the original investors but for a short period of abnormally high prices due to the war. Plants cannot be operated profitably at prices which have prevailed in 1921. The development of the industry will require very large capital expenditures, certainly without immediate return, and with little chance of a fair ultimate return unless the investment in physical properties is followed by chemical research on a scale that few organizations are equipped to undertake.

The wood is obtained from cut-over land, and is

chiefly the Southern long-leaf pine (*Pinus palustris*). This dead wood may be divided into two general classes—namely, stump and top wood. The stump wood is richer in extractable products and is correspondingly more valuable. Top wood is the upper part of the dead tree. It is a curious fact that the section of the tree from about 10 ft. above the ground to the first limbs

FIG. 2. PILED WOOD READY TO BE HAULED TO THE PLANT

is generally very poor and is culled, while above the first branches the rosin and oils are found in both the branches and body of the tree in considerable amounts. It seems to be generally true that the twisted grain wood is richer than the straight grain. This is explained, in a rather unscientific way it is true, on the ground that the oils and rosins passing through the interior of the tree are held back by the bends and gradually accumulate there. At any rate, whenever there are any twists and knots one finds extractable products in large amounts.

The distribution in the roots is also interesting. The *Pinus palustris* has two types of roots, lateral and tap. The lateral roots are close to the surface of the ground and are very rich in rosin, turpentine and pine oil; the tap root, each tree usually having but one, goes straight down into the ground. It is soft and spongy and contains practically no valuable products—in fact it is almost worthless even as fuel. It is the general belief that the tree obtains most of its moisture from this source.

In wood operations the top wood is simply cut into 4-ft. lengths and split if too large in diameter for milling. Stumps are generally blown out with dynamite. The pieces are hauled by wagons to a tram line or railroad and loaded into box or rack cars on which the wood is transported directly to the plant.

FIG. 1. BORING STUMPS JUST PREVIOUS TO BLASTING OUT WITH DYNAMITE

FIG. 3. RESERVE OF WOOD SUPPLY AT BRUNSWICK PLANT, SHOWING STACKS OF THE POWER HOUSE IN THE DISTANCE

In order for wood to be suitable for use it should age for several years; top wood requiring at least 5 years and stump wood 2 or 3 years longer. "Green" or insufficiently aged wood has been tried from time to time, but the difficulty experienced in milling is so great that its use is impractical. Furthermore, the yields are not so great as with the well-seasoned material.

Good land yields 8 to 15 tons of wood per acre, depending on the section of the country. Therefore a plant having 500 tons per day capacity would receive daily the wood from about 50 acres of land. From these figures one can obtain some idea as to the magnitude of the wood operations and of the benefits Southern agriculture will derive from this wholesale removal of stumps.

PRELIMINARY PROCESSES OF GRINDING AND STEAMING

In all the plants under the control of the Hercules Powder Co. the steam-solvent or extraction process is used. The wood is unloaded from the cars onto a conveyor which takes it to a hog or chipper, where it is cut into pieces about 2 in. long and $\frac{1}{2}$ to 1 in. thick. The hogged wood then passes directly into a hammer mill of the Jeffrey or Williams type, where the milling is completed, the wood being reduced to sizes varying from dust to pieces which will not pass through a 4-mesh screen. This milled wood is carried by belt conveyers to upright cylindrical steel tanks called extractors. These extractors vary in size at different plants but generally hold from 7 to 14 tons of wood. Charging is accomplished by means of doors at the top. A perforated plate about 3 ft. above the bottom of the extractor serves to hold up the chips. Each extractor is equipped so as to permit the use of both coils and live steam. A bottom outlet permits the solution to be "dropped" as desired.

After the extractor is filled, the first operation is to steam for turpentine and pine oil. Live steam is used on account of the high boiling point of these compounds. Each extractor is steamed for 3 or 4 hours, depending on the amount and temperature of the steam used. During this operation practically all the turpentine and about half the pine oil are distilled off, the distillate being condensed and run to a separator, where the pine oil and turpentine, being immiscible with water, are decanted off the top. This solution of "crude turpentine" has a specific gravity of about 0.880 at 15.5 deg.

C. and consists of approximately 70 per cent of turpentine and 30 per cent of pine oil. It is fractionated into commercial turpentine and pine oil by repeated distillation in ordinary pot stills. During this distillation it is necessary to use live steam, as the high temperature needed for direct distillation had a tendency to break down both compounds, causing them to darken and giving unpleasant, empyreumatic odors.

TREATMENT WITH SOLVENT

The steamed wood still contains the rosin. To remove this and whatever oils are left in the wood it is boiled with a solvent. At present gasoline is commonly used, although coal-tar products, such as benzene and toluene, have been tried to a limited extent. The great difficulty with the latter class of solvents is that they not only take out the rosin but also dissolve a large quantity of oxidized rosin, pitch and coloring matter, which renders the resulting rosin so dark that it is unfit for nearly all uses. It is evident, therefore, that the petroleum distillate has a sort of selective solubility; leaving the dark products behind in the wood and extracting only the lighter colored resinous matter.

The solvent treatment is a countercurrent proposition in which the fresh solvent comes in contact with the most exhausted chips. This solvent then goes to the chips containing a little more rosin until finally the solution is run onto wood which has been steamed for turpentine only and from which no rosin has been extracted. The resulting solution is then dropped through the bottom outlet of the extractor to the settling tank, where chips, dirt, etc., settle out.

By this process the wood is in contact with the solvent for 4 or 5 hours. The final solution usually contains about 15 per cent of rosin, although of course many factors, such as the volume of gasoline used, the percentage of rosin in the original wood and the completeness of extraction, may cause this percentage to vary greatly. It is advisable to have this solution as strong as possible so as to prevent the handling of large volumes of weak liquor.

From the settling tank the solution is pumped to evaporators. These evaporators are generally ordinary still pots equipped with steam coils and sparge pipes. During the first part of the distillation the solvent distills off and is run back to a storage tank, from which it is used again for extraction. The other frac-

Fig. 10. Air compressors at the Hattiesburg plant.

tions are high boiling and consist of mixtures of solvent and pine oil. They are redistilled to yield more solvent and an inferior grade of pine oil. The rosin remains behind in the still as a residue and is run out and poured into wooden barrels holding about 50 gal. With this type of apparatus one must use an intermittent or batch process.

In some of the plants of the Hercules Powder Co. Yaryan evaporators are used instead of pot stills. With this equipment a continuous two-stage operation is carried on, the majority of the solvent being taken off in an evaporator operating at about 50 lb. steam pressure and 20 in. vacuum, while the higher boiling liquids are evaporated at about 100 lb. steam pressure and 25 in. vacuum. The rosin is continually pumped out of the bottom outlet of the evaporator to vats, from which it is barreled as described above.

RECOVERY OF SOLVENT

After the extraction of the wood is completed, the spent chips contain about 40 per cent of their weight of solvent. This is removed by injecting live steam into the chips in a manner similar to that used in the turpentine extraction. Usually 4 or 5 hours' steaming is needed to drive off the solvent, the great difficulty being to remove the last traces. Even after this steaming there is still considerable solvent in the wood.

Analysis of samples immediately after steaming

FIG. 11. "PULLING" AN EXTRACTOR. THE SPENT WOOD GOES DOWN THROUGH THE FLOOR TO A MOVABLE BELT CONVEYOR WHICH TRANSPORTS IT TO THE FUEL BIN

have shown as high as 10 gal. of solvent per ton of spent wood, although the average is much less than that, being probably 2 or 3 gal. per ton. The accurate determination is very difficult due to the fact that when the hot chips are withdrawn from the extractor the solvent evaporates very rapidly. The loss of solvent at this point is probably the chief single source of loss in all the operation, and much valuable work can undoubtedly be done to improve this condition.

The spent wood is then "pulled" through the front door in the side of the extractor and falls to a conveyor, which carries it to the fuel bin, from which it is transported to the power house as needed. Under normal conditions the spent wood is about sufficient to give all the fuel necessary for the operation of the plant.

It may be seen from the above description that the whole operation is by no means simple. Provision must be made for an adequate supply of wood at all times. To do this it is necessary to have a wood force double

that required to operate the plant. On account of the frequent rains which slow down the wood operations for weeks at a time, the plant should always have a large supply of reserve wood on hand. The same may be said of solvent. Under normal conditions about 8 to 10 gal. of solvent is lost per ton of wood worked. This means that several thousand gallons must always be in reserve. In addition it may be roughly estimated that 200 gal. of solvent is required for every ton of wood worked—that is, for a hundred ton plant 20,000 gal. must be kept in the system. As both the solvent and manufactured products are very flammable, great care must be taken to prevent fires.

STEAM-DISTILLED WOOD TURPENTINE

The products obtained from this process are, as mentioned before, turpentine, pine oil and rosin. The turpentine is sold on the market as steam-distilled wood turpentine to distinguish it from the spirits of turpentine or gum turpentine, which is made from the gum of the living tree, and from destructive turpentine, which is made by the destructive distillation of dead pine wood. Formerly wood turpentine was looked upon with disfavor by the paint and varnish trade, but since the product meets the highest specifications required commercially, this prejudice has been almost entirely overcome.

One of the great advantages of the better grades of wood turpentine is its uniformity. This is especially true of the output from well-equipped plants where a careful chemical control is maintained. In the Hercules plant the present Navy specifications are used as a standard which the turpentine must meet. A typical analysis of this product is as follows:

Initial boiling point.....	154 deg. C.
Per cent boiling below 170 deg. C.....	90.5
Polymerization residue	1.0
Specific gravity at $\frac{15.5 \text{ deg. C.}}{15.5 \text{ deg. C.}}$	0.865
Color	W.W.
Flash point (Abel closed cup).....	34 deg. C.
Refractive index at 15.5 deg. C.....	1.469

A comparison of wood and gum turpentine is not particularly easy on account of the variation in both products. If, however, the above analysis is taken as typical of wood turpentine, one can say that the refractive index and specific gravity are in most cases higher in gum than in wood turpentine. Furthermore, gum turpentine, especially when freshly distilled, has a fragrant, sweet odor, absent from wood turpentine. This is supposed to be caused by certain esters and aldehydes present in the gum. Turpentine loses much of this fragrant odor on standing. Wood turpentine, due to the fact that it is always redistilled, generally has a better color than gum turpentine, which is barreled directly from the still without redistillation.

PINE OIL AND ITS CHARACTERISTICS

Pine oil is perhaps the most interesting of all the products. While in the gum industry no pine oil is obtained, yet in this process about 1 part of pine oil to 2 parts of turpentine is recovered.

This pine oil when first produced was considered practically worthless. In later years, however, it has become valuable in many ways. In the flotation field it is one of the best frothing oils known and great quantities are used yearly for this purpose. It is the basis of a variety of medicinal and disinfectant solutions. The rubber industry consumes quantities for various purposes. The paint and varnish industry has also made use of the

peculiar properties of pine oil. Toch¹ makes the following comments on the application of pine oil: "It has been used to a considerable extent for making paints which should dry without a gloss, and as a "flatting" material it has been successful. It has the excellent quality of flowing out well under the brush and of not showing brush marks, the latter because it evaporates so very slowly. It is a very powerful solvent, and many of the acid resins which have a tendency to separate when they are insufficiently cooled with drying oil will remain together when pine oil is added."

A high-grade commercial pine oil manufactured at Brunswick, Ga., had the following analysis:

Boiling range	180 deg. C.-225 deg. C.
Specific gravity at 15.5 deg. C.....	0.935
Color	Light straw
Refractive index at 15.5 deg. C.....	1.479
Polymerization residue	3 per cent

COMPOSITION OF PINE OIL

The composition of pine oil is rather uncertain. It was at first thought to be a hydrocarbon similar to pinene, but later Teeple² and Toch¹ showed that the pine oil was very similar to terpineol, $C_{10}H_{17}OH$.

Toch found that a pine oil of 0.942 gravity contained 78.1 per cent C, 11.5 per cent H and 10.4 per cent O, while the theoretical for terpineol is 77.68 per cent C, 11.77 per cent H and 10.38 per cent O. A sample of pine oil, analyzed at our experimental station, having a gravity of 0.933 and a boiling range of 180 deg. C. to 225 deg. C., showed 80.7 per cent C, 10.9 per cent H and 8.4 per cent O. It is probable that some hydrocarbons were present. In fact the commercial pine oil undoubtedly consists of several distinct compounds.

The origin of pine oil is still a mystery. Dr. Toch believes it is due to hydrolysis and oxidation as a result of exposure to the atmosphere. We are inclined to the belief that pine oil is present in the living tree as an essential oil, and is not a product of hydrolysis or oxidation. It is our intention to study this interesting problem very shortly.

FIG. 12. DIPPING ROSIN FROM VATS INTO BARRELS. THIS IS THE GENERAL PROCESS USED IN BOTH GUM- AND WOOD-ROSIN INDUSTRIES

Rosin is the chief product extracted, since approximately a standard barrel of rosin (280 lb. gross) is recovered from 1 ton of wood. As usually obtained it is a ruby red product. The red color is peculiar to this grade of rosin, and many theories have been advanced as to its origin. We believe that the greater part of this red color has its origin in forest fires, with a resulting decomposition and oxidation of the wood and rosin. This theory is based on the following experiments:

If one removes the outer portion of a stump, extracts the inner part with gasoline and evaporates the solvent, the rosin obtained will have only a small amount of red coloration. If, however, the wood is charred and then extracted, it will give a rosin with the characteristic dark red color. Rosin extracted from the living tree will also show comparatively little of this red color, but it is not a lighter grade of rosin than that taken from the interior of a stump.

Rosin is considered to consist principally of abietic acid, the formula of which is generally given as $C_{20}H_{30}O_2$. Several ultimate analysis were made at our experimental station in order to learn how closely wood and gum rosins correspond to the above formula. These gave the following percentages:

Product Analyzed	C	H	O
Gum F	77.41	9.56	13.03
Gum W.W.	78.78	10.38	10.84
Wood rosin (Yaryan F).....	78.12	9.90	11.98
Abietic acid (prepared in lab.)....	79.34	10.18	10.48
Abietic acid (calculated $C_{20}H_{30}O_2$)...	79.41	10.01	10.58

These results show that both wood rosin and gum rosin correspond very closely to abietic acid. It is an interesting fact that, judging from these analyses, the wood rosin does not appear to contain as much oxygen as ordinary gum rosin and is not, as commonly supposed, a highly oxidized rosin.

COMPARISON OF WOOD AND GUM ROSIN

The following is a comparison of the common analytical constants of gum and wood rosin:

Rosin	Acid No.	Saponification No.	Ester No.	Unsaponifiable, Per Cent
Yaryan F...	147.7	162.7	15	7.3
Gum F.....	155.9	174	18	4.8
Gum W.W..	154.7	182.8	28.1	5.1
Gum F.....	162.4	176.4	12.0	5.2
Yaryan F...	150.5	170.9	20.4	6.0

As with wood turpentine, there has been some prejudice against wood rosin among users. Probably this objection has been justified in the past, as the earlier products in many cases were very inferior. By reviewing the process one can see that there is a possibility by careless operation both of contaminating the rosin with solvent, which will obviously soften it, and of unduly darkening the rosin by overheating. Both of these faults were of common occurrence during the pioneer work. With careful operation, however, one can be assured of a very uniform product, particularly free from foreign matter. While the color prevents its use for some purposes, yet under most other conditions it doubtless has an advantage over gum rosin because of its uniformity and cleanliness.

At present the production of naval stores from this source is only about 10 per cent of the total output, and is consequently of comparatively minor importance. However, with the growing shortage of living trees and the consequent diminution of the supply of gum product, this industry in the future will play an important part in the production of naval stores.

Importance of the Olefine Gases and Their Derivatives

III—Ethylene Dichloride*

A Commercially New Extraction Agent Prepared From Ethylene and Liquid Chlorine, Having Properties Approaching Those of an "Ideal" Solvent—Chemical Stability—Sharp Boiling Range—Low Fire Hazard—Physiological Properties

By GEORGE O. CURME, JR.

WHILE ethylene dichloride stands as one of the earliest organic chemical compounds isolated and described, its application in the chemical industry to the purposes for which it seems by nature so well fitted has never reached proportions to make its name known among a majority of the industrialists. Why this should be is one of the unexplained mysteries of chemical technology; for, while this material has remained unrecognized technically, at the same time a wide search has been made by chemists for a substance of almost its identical properties to amplify the very restricted number of commercial solvents now at the command of our extraction industries. It was through the first synthesis of this substance from ethylene and chlorine by four Dutch chemists¹ that the name of "olefines" (oil-forming) was given to the entire series of homologous ethylene hydrocarbons. This name has lived, but the material itself has been pushed to the back shelves of our chemical museums, where it has been apparently overlooked in this search. It may be that a lack of knowledge of convenient technical processes for its production has caused this neglect. In any event, that this material is now on the market as a product of the rising olefine gas industry is an item which should interest many industrial chemists, seeking for new possibilities with new commercial materials.

Since the first production of ethylene dichloride in 1795, it has frequently been the subject of academic investigations. Its properties have been accurately catalogued, its sources of production have been described, and through the limited number of reactions which it has been shown to undergo its chemical stability has been demonstrated. This compound ($C_2H_4Cl_2$) has been variously known as "Dutch liquid," "elalylchloride," "ethylene chloride," "ethylene dichloride" and also by the more exact term "1,2-dichloroethane." Of these names, ethylene dichloride is perhaps the most used and is most descriptive of its method of preparation. When pure, it is a colorless liquid, with a pleasant, chloroform-like odor. It boils at 83.5 deg. C. at 760 mm. and on cooling to a low temperature forms crystals which melt at -36 deg. C. It has the density, $D_{40}^{20} = 1.2569$; the specific heat of 0.3054 at 30 deg. C.; and the latent heat of vaporization of 157.5 B.t.u. per lb. at 0 deg. C.

Of the various methods of preparation of ethylene dichloride the only one of commercial importance is

the direct combination of ethylene and chlorine. This reaction takes place readily under a variety of conditions, and different combinations of these conditions have formed the basis of recent patents,² which, however, do not seem to have been operated successfully to date. In the earlier described processes gaseous ethylene and chlorine were simply permitted to mix in a vessel, the liquid product condensing out as formed. In this procedure, however, the rather considerable heat of reaction caused the reacting gases to assume a temperature much above normal with an attendant continuation of the reaction to form higher chlorinated products, such as trichlorethane. Then, too, this reaction is slow and requires a large reacting volume for a given production. Modifications of this reaction have been suggested, such as to cool the reacting gases and to use catalysts such as moisture³ or calcium chloride.⁴

Brooks and Smith⁵ have suggested the use of chlorine dissolved in a solvent for the production of mixed ethylene and propylene dichlorides from oil gas and also the use of sulphuryl chloride as a chlorinating agent for unsaturated hydrocarbons from oil gas. In the writer's work it has been found that when dry ethylene and liquid chlorine are brought into contact with each other there is a rapid and exceedingly smooth formation of ethylene dichloride.⁶ This reaction is carried on preferably at temperatures somewhat below 0 deg. C. and at a pressure corresponding to the vapor pressure of chlorine. There is very little further chlorination of the ethylene dichloride, even though held for some time in an excess of liquid chlorine—an excellent example of the stability of this substance. As a byproduct, ethylene dichloride has been found in the production of other materials also produced by the chlorination of ethylene—e.g., ethylene chlorhydrin and mustard gas (β, β' -dichlorethyl sulphide). Also it has been described as occurring in the mixture found in the manufacture of carbon tetrachloride from carbon disulphide, and also from the chlorination of natural gas. A limited quantity of ethylene dichloride has been offered on the market within the past few years, but from just what source it is not known to the writer.

Investigations in the past have shown that chemical derivatives of ethylene dichloride can be made. Regnault described the production of vinyl chloride by action of alcoholic potash on this material.⁷ Matter,⁸

Hough,⁹ Brooks¹⁰ and Hilbert¹¹ have shown that glycol can be made by hydrolysis with an alkali or alkali salt at elevated temperatures. Boehringer¹² describes the formation of ethylene diamine with liquid ammonia and at high temperatures. However, these extreme conditions necessary to bring about reaction in the above instances, as well as the method of production mentioned above, show clearly that it is among the most stable of the simpler organic compounds.

SOLVENT PROPERTIES

This characteristic of ethylene dichloride, in addition to its high solvent action on oils, fats, waxes and certain resins and gums, points clearly to its qualifications as a solvent. The solubility of these materials in the chlorinated solvents as a class is already too well known to need detailed description and for general purposes ethylene dichloride ranks among the best. Dr. L. H. Baekeland,¹³ in his Chandler Foundation lecture in 1914, speaks very highly of the value of this material as the chlorinated solvent of the future.

RESISTANCE TO HYDROLYSIS

In a comparison with other chlorinated solvents, the outstanding characteristic of ethylene dichloride is its chemical stability above mentioned and its resistance to hydrolysis under conditions of solution and extraction. The hydrolysis of carbon tetrachloride to break off hydrochloric acid in extraction work where water is present is well known, and has unfortunately resulted in serious damage to iron- and lead-lined extraction equipment. The commercial chlorinated solvents derived from acetylene—namely, acetylene tetrachloride, trichlorethylene and dichlorethylene—which must not be confused with the above, are also subject to the same objection, though to a lesser degree. Ethylene dichloride, alone of all the chlorinated solvents, may be safely handled in presence of water at a boiling temperature, in iron or other metal vessels without danger of damage from corrosion. In confirmation of this freedom from destructive effect, tests on corrosion by organic halides published by Doughty¹⁴ show ethylene dichloride as the only one of the commercial chlorinated solvents examined which did not reveal corrosive action under the condition of the tests made.

The relatively lower density of this solvent is favorable to its use, as the cost per volume of liquid used is thus lessened. The boiling point of 83.5 deg. C. is ideal for most purposes, permitting a complete removal of the solvent without excessive temperatures, and yet permitting easy condensation and giving minimum loss on handling. As a commercial product it can be supplied in high purity; therefore instead of boiling range of many degrees it will boil sharply at a given temperature. This feature avoids one of the main objections of most commercial solvents—namely, that of leaving a "heavy end" in the extract as well as in the residue.

Again the stability of ethylene dichloride is shown in its resistance to oxidation. Many of the chlorides of carbon when kept in a partly filled container split off hydrochloric acid and give an oxidized product; for instance, in the cases of chloroform and carbon tetrachloride the poisonous phosgene is formed under such conditions. With ethylene dichloride this oxidation does

not occur to a noticeable extent; accordingly no preservative is needed, it may be re-used indefinitely, and no unpleasant odor or flavor is given to edible products.

The above characteristics recommend this solvent particularly for the extraction of edible oils and other products where highest purity is a prime requisite. A further application in the extraction of grease from wool seems to offer promise as well.

In quite another line of solvent work where it is desirable to use a strongly reactive substance in solution, the stability of ethylene dichloride is of advantage. In such reactions where free chlorine, sulphuryl chloride, sulphur monochloride and other active reagents are to be used in solution, ethylene dichloride may safely be used as a solvent without being affected.

LOW FIRE HAZARD

It has been found that ethylene dichloride will support combustion when ignited in the air, but only with difficulty. It is a compound just on the border line of the fire-extinguishing chlorinated hydrocarbons and the combustible hydrocarbons. In many cases when ignited the draft from the combustion will blow out the flame, so weak is the tendency to burn. In any case, as regards industrial use, being heavier than water, it is therefore extinguished by water in contradistinction to benzene or gasoline.

PHYSIOLOGICAL PROPERTIES

The effect of inhaling the vapor of ethylene dichloride is not dangerous, although, as in the case of any organic solvent, it is to be avoided as far as possible in high concentrations and for extended periods. In earlier days of medicine this substance was in actual use as an anæsthetic,¹⁵ which of itself demonstrates that there need be no serious after-effects from its inhalation, even though carried to the extreme point of loss of consciousness.

It is interesting to note that in current articles on matters relating to the solvent extraction and related industries the matter of the solvent is given great importance. In particular, the need of an "ideal" solvent is emphasized. The writer is quite willing to admit that such perfection is not to be hoped for in any material of chemistry; but as a solvent that approaches the ideal, it is quite possible that it will be found that this has been contributed by the olefine gas industry in ethylene dichloride.

SUMMARY

The characteristics of ethylene dichloride which recommend it for use in extraction and solvent work are:

1. It is an excellent solvent for oils, fats and greases.
2. It is a pure chemical with constant boiling point.
3. It can be removed completely from both extracts and residue, leaving no unpleasant odor or taste.
4. Its density and heat of vaporization are low.
5. Its stability permits indefinite re-use and freedom from chemical action on materials treated.
6. It does not corrode metal, even in presence of water at the boiling point.
7. It may be used without danger to workmen.
8. It presents a very low fire hazard.

(Part IV, dealing with isopropyl alcohol, will be published in a subsequent issue.)

¹⁵Gwathmey, ("Anesthesia," Appleton, New York, 1914, p. 749) states: "Its [ethylene dichloride] anæsthetic action was first studied by Simpson in 1846, Snow in 1848, Clover in 1848 and Richardson in 1851. The latter regarded it as a good anæsthetic, very much like chloroform in its action, although less rapid."

On the Theory of the Hardening of Metals

The Japanese Scientist Thinks That Hardness in Metals Is Due in Part to Forces Between Atoms and in Part to an Interlocked, Strained Crystalline Structure—Heat-Treatment of Duralumin Is Quite Similar to That of Steel

By KOTARO HONDA

Tōhoku Imperial University, Sendai, Japan

IN this journal for June 15, 1921, vol. 24, p. 1057, Zay Jeffries and R. S. Archer have written an interesting article entitled "The Slip Interference Theory of the Hardening of Metals," explaining by their theory many complicated phenomena regarding the hardening of steel by quenching, as well as the aging of duralumin after quenching. The essential feature of the theory lies in the assumption that the internal slip in the metal caused by stress is hindered by the presence of fine, hard particles scattered uniformly throughout the mass, and hence the metal is greatly hardened. However, this assumption is not very probable, when the quantity of hard particles amounts only to a few per cent of the whole mass.

To take a simple analogy, do we know how much gelatin becomes hardened when mixed with a few per cent of fine sand or fine grains of some compound? On the other hand, where hard particles contain only a few per cent of gelatin or other cementing material, the whole mass becomes considerably hard. In a solid solution, the solute is distributed, in particles no larger than an atom, among the atoms of the solvent according to the space-lattice of the latter, and hence the analogy between a metal containing hard particles of much larger size and the solid solution can no longer hold, as the conception denoted by the word "hard" is not applicable to the atoms themselves. Hence the slip interference theory should not be extended to the case of solid solution.

INTERMOLECULAR FORCES

In a solid substance, the molecular force exerted in an atom from one of its neighbors consists of an attraction and a repulsion; if it were mere attraction, all the atoms will collapse into a single compact mass. Thus the expression of the molecular force between two atoms will be given by an expression, for example, of the form

$$F = \frac{am}{r^\mu} - \frac{bm}{r^{\mu+\nu}}$$

where m is the mass of the atoms, r is the average distance apart, a and b are both positive constants characteristic of the substance, μ and ν are positive values probably greater than 3. Since atoms have a complex structure, it is easy to understand that μ and ν are not constant for wide variations in the separating distance and especially when the atoms are placed close together, their values depending on the distance and orientation of the atoms. At a very small distance the second term measuring repulsion predominates, while at a relatively large distance the first or "attraction term" prevails. When no external force acts on the substance, the resultant force acting on any one of the atoms is zero.

A hard substance may therefore be defined as one for which a small variation of the relative configuration of

the atoms causes large forces between atoms; that is, $\frac{dF}{dr}$, or a , b , μ and ν are large. It is also evident from this consideration that the hardness or strength of a substance changes when it undergoes an allotropic transformation. To take a concrete example, martensite, which may be considered as an allotropic modification of austenite, has a great hardness as compared to the latter. According to the result of X-ray analysis, the atomic distribution of austenite is as a face-centered cube, while that of martensite is a body-centered cube; thus the atoms in austenite are in the closest packing. As the hardness of a solid solution is largely measured by the value of $\frac{dF}{dr}$, it is quite possible that a distribution having a less close packing of the atoms—martensite—has a greater hardness than that of the closest packing—that is, of austenite.

TWO DISTINCT KINDS OF HARDNESS

The present author's theory of hardening¹ differs wholly or in some respects from some of the other existing theories—that is, β iron theory, the amorphous theory, the solid solution theory, the interstrain theory, and the slip interference theory.

It is first of all necessary to differentiate hardness into two classes according to its origin:

(I) Hardness due to molecular force.

(II) Hardness due to the crystalline structure of metals.

Consider Class I. A pure metal or solid solution is homogeneous; for such substances, the hardness must depend solely on the molecular force, as already explained above. In this case, Tammann's theory² of the hardness of solid solutions is quite correct. If two metals are able to mix with each other in all proportions, then the hardness of the alloy generally exceeds that of either of its components, and this hardness has a maximum in an alloy containing an equal atomic quantity of the components. The very fact of miscibility of two metals indicates that the molecular force and its gradient acting between the molecules of different metals are greater than those acting between atoms in the pure metal; and therefore if the two metals form an alloy, the molecular force due to the change of atomic configuration (that is, the hardness) will be greater than that in the respective metals and be maximum in the alloy corresponding to an equal atomic quantity of the components.

Next, let us consider that hardness due to the crystalline structure.

¹K. Honda, *Sci. Reports*, vol. 6, p. 95 (1917).

²Lehrbuch der Metallographie, p. 332 (1914).

Suppose a metal to consist of an immense number of acicular or needle-shaped crystals, which are imbedded in a homogeneous component or in a solid solution and have their lengths all parallel to one another. Such metal very strongly resists tension acting in the direction of the needle crystals, but only weakly the pressure acting perpendicularly to them. This can easily be understood from the analogy of a wire, which can resist a strong tension, though it bends by a small force acting perpendicularly to its length. If the direction of the axes of needle-shaped crystals be uniformly distributed in all directions, then the metal will resist indentation by the Brinell ball very strongly, for the compression will result in stretching a certain fraction of the whole number of needle-like crystals and therefore produce tension in these crystals. A good illustration will be found in the case of the wheels of a bicycle, in which a certain number of spokes radiate from a common center toward the circumference. It is well known that although the spokes are very thin, the wheel can resist a great tension or compression acting in any direction. Hence if a metal contains fine acicular or needle-shaped crystals and their axes are uniformly distributed in all directions, the metal is very hard. By this theory, a metal is harder as its structure is finer and the crystals are in a highly stretched state.

HONDA'S THEORY OF HARDNESS

The above theory may be briefly expressed in the following words: For a given substance having a definite molecular force, its hardness increases with the fineness and the strained state of structure; and for the same structure and the same degree of strain, the hardness of a substance increases with the strength of the molecular force developed by a given change of the configuration in the atoms. This theory, though it is very simple, explains many observed facts in a very satisfactory way. Thus the hardness of solid solution of cementite in iron is partly due to fine martensite or acicular crystals cemented together. These fine crystals will probably be left in highly strained states by rapid cooling, like tightened spokes of a bicycle, thus further increasing the hardness of the solid solution.

Hardening by cold-working or overstraining is also explained in a similar way. This process is analogous to that of tightening the spokes of the bicycle wheels to insure its solidity. Cold-working or overstraining puts fine crystals in a highly stretched state; this state corresponds obviously to the hard state of the substance. In this respect my theory coincides with the interstrain theory; the latter, however, does not explain why interstrain causes greater hardness of the substance, but in my theory this is explained by a well-known mechanical property of the material. By annealing a specimen which has undergone cold-working, the strained state of the minute crystals is released, grain growth takes place, and therefore the hardness decreases on both accounts.

WHAT IS MARTENSITE?

In the theory of hardening this important question arises: Why on quenching a steel in the austenitic state is a martensitic structure instead of an austenitic or pearlitic structure obtained? In metallurgical investigations we very often use the principle that by quenching a metal from a high temperature the structure at this temperature is preserved at room temperature, but the formation of martensite is an exception to this principle, and we feel a great uncertainty with

regard to the general result of many heat-treatments. Some metallurgists have considered martensite to be an indefinite semi-transformed substance; but considered from the result of recent investigations, we must consider it to be a perfectly definite phase. From X-ray analysis it is to be concluded that martensite is a different phase from austenite and also that although martensite has the same atomic distribution as ferrite, at least with respect to iron atoms, it contains carbon in solid solution, hence is different in phase from ferrite.

According to the result of some experiments made at the Tôhoku Imperial University which have not yet been published, the heat of transformation from martensite to pearlite is definite and proportional to the content of carbon, amounting to about one-third the heat liberated at the A_1 transformation. This also indicates that martensite has a definite structure. The fact that the hardness and specific volume of martensite are very large in magnitude as compared to both austenite and pearlite disproves the conception that martensite is an intermediate stage of the transformations from austenite to pearlite (or in a strict sense from austenite to troostite).

THEORY OF QUENCHING

Having thus far cleared the nature of martensite, we now proceed to consider the theory of quenching.³ According to my opinion, the so-called A_1 transformation is not a simple but a compound transformation consisting of

Thus, during a slow or rapid cooling, austenite is at first changed into martensite, which is then transformed into pearlite. During a slow cooling, austenite changes into martensite, and the latter, being at a very high temperature, changes immediately into pearlite. But during a very rapid cooling, such as quenching, the change from austenite to martensite is so far retarded that when this change is completed the specimen is nearly at room temperature, and therefore the next change from martensite to pearlite cannot progress, owing to the high viscosity of the material at that temperature. Hence quenching produces a hard martensitic structure. During heating, the A_1 transformation also consists of the reverse changes—that is, from pearlite through martensite to austenite.

In the above conception it is obvious that the general principle that quenching preserves the state stable at the elevated temperature is not violated in the least by the formation of martensite by quenching. If the quenching is too severe, even the first transformation from austenite to martensite is partly prevented, and therefore at room temperature we obtain a martensitic structure containing a certain amount of austenite. This austenite has a tendency to change into martensite, and in fact changes very slowly at room temperature. Hence the hardness of a severely quenched steel increases with the lapse of time, as has actually been observed.⁴

If the quenched steel be heated at 100 deg. C., the above transformation from austenite to martensite is accelerated, and therefore the increase of hardness goes on more rapidly than at room temperature. But if the heating temperature is too high, say 300 deg., not only the first change but also the second change from marten-

³K. Honda, *Sci. Reports*, vol. 8 (1919), p. 181; *Iron & Steel Inst.*, No. 1 (1920).

⁴K. Honda and S. Idei, *Sci. Reports*, vol. 9 (1920), p. 491.

site to pearlite begins to take place, and therefore the hardness decreases as a whole—that is, the steel is tempered.^{4,5}

It is quite natural that the A_1 transformation consists of a double change

Austenite $\rightleftharpoons$ Martensite $\rightleftharpoons$ Pearlite

as is readily seen from the following considerations: From the standpoint of X-ray analysis, it is highly probable that both austenite and martensite are solid solutions of carbon, but not cementite, in iron. But the separation of carbon from its solid solution takes place as cementite; hence for its separation (that is, for the A_1 transformation) austenite will first change into martensite, a configuration more favorable for the separation of carbon as cementite, and then follows the separation of cementite, or what is the same thing, the transformation of martensite to pearlite. As shown below, a similar stepped change also exists in the case of duralumin.

An investigation of duralumin by S. Konno⁶ resulted differently from those of P. D. Merica, R. G. Waltenberg and H. Scott⁷ in some important points. The following are the chief results of his investigation:

RESULTS OF INVESTIGATION OF DURALUMIN

1. In quenched duralumin, the softer the quenching the greater the immediate hardness increase, but the gain in hardness by aging as well as the final hardness decreases. In a quenching in oil at 100 deg. C. or higher temperature the aging effect vanishes. On the other hand, the more drastic the quenching the immediate hardness decreases, but the aging effect and the final hardness increase, their maximum values being obtained by quenching the alloy from 500 deg. C. in water.

2. The above effect of quenching is due to the precipitation of copper and magnesium compounds from the aluminum, the process of separation being very slow. Thus duralumin is in a somewhat hardened state; even if it is cooled very slowly from 500 deg. C., a perfect annealing is obtained only by heating the alloy at 350 deg. C. for 1 hour or more.

3. Up to about 6 per cent Cu, alloys of Al and Cu show by quenching an immediate hardening, but very little effect on aging. Hence the immediate hardness is partly due to the precipitation of CuAl_2 in Al.

4. With an addition of a small quantity of Mg (0.7 per cent) to the above alloys, an immediate hardening as well as an aging effect becomes prominent, and nearly of the same order as in duralumin. A further addition of manganese increased the quenching effect, viewed as a whole.

5. The aging after quenching is attributed to the precipitation of Mg_2Si from the solid solution of CuAl_2 in Al. It is not due to metallic magnesium, because a mere increase of Mg does not result in an increase of aging effect, but an increase of both Mg and Si in the proportion of the compound Mg_2Si magnifies the same effect. As a matter of fact a small quantity of Si (0.5 to 0.7 per cent) is always present in Al as an impurity. The content of Si being assumed to be 0.7 per cent, the effect of quenching, if Mg increases beyond 1 per cent, begins to diminish, and almost vanishes above 3 per cent Mg.

The last three results, 3, 4 and 5, differ from those by Merica, Waltenberg and Scott.

6. From the specific resistance versus temperature curves for quenched duralumin, we conclude that the quenched alloy is tempered at two steps beginning at 210 and 280 deg. respectively. The first step in the curves is due to the partial separation of CuAl_2 , and the second to that of Mg_2Si .

7. Quenched duralumin expands at room temperature as the aging proceeds, thus being similar to quenched low-carbon steels.

ESSENTIAL SIMILARITY IN PROCESS WHEN HARDENING STEEL AND DURALUMIN

The above effect of quenching and the accompanying change of physical properties are quite similar to those in severely quenched carbon steels. Hence we can explain the hardening by quenching in exactly the same way as in steels.

As stated above, duralumin contains two compounds, CuAl_2 and Mg_2Si . Hardening resulting from quenching may be considered as the effect of Mg_2Si in the solid solution of CuAl_2 in Al. The solubility of Mg_2Si begins at about 350 deg. and rapidly increases with the rise of temperature. Let us call CuAl_2 : Al solid solution containing dissolved Mg_2Si the γ state and that containing Mg_2Si as a mixture the α state. As in the case of cementite dissolved in iron, the separation of the compound is assumed to take place in two steps—that is, γ solid solution is at first changed into β solid solution, whose atomic configuration is favorable for the separation of the compound, and which is also very hard as compared to γ or α state, and then the separation of the compound from β follows. In conformity with the observed facts, the transformations

are assumed to progress very slowly.

According to the above theory, by quenching duralumin in water even the first transformation from γ to β is partly arrested, and we obtain β mixed with γ at room temperature. Gamma state, thus quenched, changes at room temperature very slowly into a hard solid solution β ; but β changes into α scarcely at all. The consequence is that by quenching, the alloy is hardened and its hardness increases with time. Thus the immediate effect of quenching is determined by the quantity of β present, and the aging effect by that of γ .

If the quenching is very severe, a larger part of γ is preserved at room temperature, only a small remainder being β , so that the aging effect is very large, but the immediate hardness effected is small. As the quenching becomes less drastic, the quantity of β at room temperature increases and that of γ decreases; hence the immediate hardness increases, but the aging effect decreases.

By heating the quenched specimen at a temperature higher than room temperature, say 100 deg. C., the transformation of quenched γ into β is accelerated, so that aging takes place in a comparatively short time, as actually observed. But if the heating temperature is too high, say 300 to 350 deg. C., not only quenched γ is changed into β , but also the second transformation of β into α takes place comparatively rapidly, so that the hardness decreases as a whole. This is a case of tempering. The above explanations are given by way of examples, but all results observed are equally well explained by the above theory.

Auxiliary Electrochemical Developments for Hydro-Electric Plants

BY H. K. BENSON

AUXILIARY electrochemical plants offer many interesting possibilities for the utilization of the off-peak power of municipal hydro-electric developments. In the few instances where such combinations are in operation the load factor has been very favorably advanced.¹ For economic reasons there is always a certain reserve of power and always a certain amount of water going over the spillways. In the Pacific Northwest the seasonal water flow also offers an attractive inducement for an industry that can accommodate itself to the varying supply of power. The characteristics of such an industry are somewhat peculiar. First, there should be no heavy investment of money in machinery or plant, inasmuch as when the power site is fully developed there may be only a comparatively small amount of power for side consumption. Moreover, during certain years there will be no high water, a condition which would lead to the necessity of using all the storage water for power purposes for the regular load. Second, the industry must be of such a nature that it will run on intermittent power and the process must be such that it will be capable of regular shut downs. This is due to the fact that in most daily load curves of power plants there are three peaks or maximums and the power going to the side industry must lie in between these peaks.

An analysis² of the chemical processes utilizing electrical power shows only a limited number capable of operating under the conditions above enumerated. For convenience these processes may be divided into two general classes: electrolytic and electrothermal.

ELECTROLYTIC INDUSTRIES

The electrolytic industries consist of the following: (1) Refining processes in which crude metals are deposited on pure cathodes; (2) reduction and oxidation processes for the production of many organic materials; (3) fused metal processes such as the production of aluminum, calcium and sodium, and (4) the caustic potash and soda industries. Refining processes for the metals are carried out under acidic conditions and are not suitable for interrupted power, while the fused metal processes require cells of high heat capacity and consequently not adapted to variable power supply. The oxidation and reduction processes used in the manufacture of vanillin, hydroquinone, para-amidophenol, alizarine, saccharine, aniline blue, congo red and other organic chemicals might in some cases operate on the off-peak loads. But the most important processes which can utilize such loads are those involving the electrolysis of solutions as in the manufacture of caustics, hypochlorites, alkali metals, bromine, fluorine, chromium sulphates, perchlorates, hypochlorites, hydrogen and oxygen. In the caustic industry, for example, two factors are in its favor, since, first, all the extra capital requirement would be confined to the automatic valves to cut off the brine supply when the current from the power plant is needed for the peak load and second, these cells are capable of coming up to normal efficiency in from three-quarters of an hour to one hour.

These processes may be grouped under four classes

according to the manner in which electric energy is transformed into the heat energy required for the chemical reaction. These groups are: (1) The arc, which yields the highest temperature and confines the heat to a comparatively small region; (2) resistance furnaces used in the manufacture of abrasives and of iron; (3) the combination arc and resistance processes used in the manufacture of phosphorus and carbon disulphide, and (4) the induction furnaces used in steel manufacturing. Of these processes the arc seems the most suitable for the intermittent power load. It has been thus used successfully for the fixation of atmospheric nitrogen and has been recommended by the British Ministry of Munitions to the House of Parliament for use in England.³

In the selection of an industry for the utilization of off-peak power the first choice would lie in the arc process, because of the great advantage the arc process holds over all others due to its low heat capacity and the fact that the cost of production is largely dependent on the cost of power. Second choice rests in the electrolytic processes excepting only the refining of metals. Although their capital requirements are high, depreciation is small and the low price of off-peak power is quite a factor in their costs of production. The third choice lies with the processes using the combined arc and resistance furnace under conditions where seasonal power would be available to maintain the necessary heat capacity of the furnaces continuously or where the margin of reserve power could be similarly utilized.

RECOMMENDATIONS FOR SKAGIT PROJECT AT SEATTLE

A detailed study of the particular chemical industry to become an auxiliary of a given hydro-electric plant involves of course its location with respect to raw materials and markets for the products. A careful analysis of such conditions in the case of the new Skagit hydro plant under construction by the city of Seattle has led to the following conclusions:

1. The most suitable means for increasing the load factor of the Skagit project would be the fixation of nitrogen by the electric arc.
2. The production of phosphoric acid by electrochemical means would be the second choice.
3. Hydrogen and oxygen as produced in the electrolytic cell would rank third in suitability excepting only under the condition that there would be established in or near Seattle a hydrogenation industry, in which event this electrolysis would rank second if not first.
4. The electrochemical production of caustic and allied products or of organic chemicals takes fourth place in utilizing the power wastage of the Skagit project.

It is obvious from data gathered in this investigation that close co-ordination between the chemical and electrical engineers in the development of hydro-electric plants will bring forth results of mutual value in the development of these newer phases of industry.

Recent Developments in the Sulphuric-Acid Industry—IV*

Description of Two New Types of Nitration Processes for Producing Sulphuric Acid Without the Use of Lead Chambers—Adsorptive and Catalytic Properties of Silica Gel—Conclusion

By ANDREW M. FAIRLIE
Consulting Chemical Engineer

THE first serious attempt to manufacture sulphuric acid by a nitration process without the use of lead chambers was the invention of Opl, of Hruschau, Austria, patented in the United States in 1911. The Opl process made considerable headway in Europe, but it received little attention, in a practical way, in this country. Recently two other nitration processes, without chambers, have been proposed, and at least one installation of each type has been erected. These two processes are the Kaltenbach pipe process and the so-called "packed-cell" process.

THE KALTENBACH PIPE PROCESS

M. Kaltenbach, after careful consideration of the thermal balances between the heat entering and leaving (a) the Glover tower; (b) the first two chambers out of a total of four; and (c) the last two chambers, came to the conclusion that the defects of the chamber process were the impossibility of obtaining throughout a set of chambers the most favorable reaction temperatures; the unsatisfactory contact between the reacting gases and liquids; the inefficiency of the lead surfaces for the dissipation of heat; and the bulky and expensive construction.¹⁶

To overcome these defects the pipe process was devised and patented by Kaltenbach. Its main characteristics are: (1) The dissipation of the evolved heat in the immediate vicinity of its generation. (2) The possibility of regulating both the reaction temperature and the acid concentration simultaneously to obtain the most favorable conditions. (3) Intimate contact between the reacting gases and liquids.

The apparatus consists of a multiplicity of pipes or tubes packed inside and water-jacketed outside. The gases leaving the Glover tower proceed through the tubes of successive systems, in counter-current to the acid, which is mixed as required with appropriate quantities of water. The gases are fed to the parallel tubes comprising any group in a series, through a common header, and devices are provided to assure the regular distribution of acids and gases in the tubes. The dimensions and the shape of the tubes have been carefully designed so that the cooling effect of the water jacket

may be felt at the center as well as at the walls. The number of tubes installed depends on the volume of gases to be treated.

The following description of the apparatus is taken from the abstract of Kaltenbach's paper:

"In the figure (Fig. 33), which is a diagrammatic representation of this apparatus for making sulphuric acid, 1 is the Glover tower which receives through the pipe 2 the hot gases coming from the furnaces and which discharges these gases through pipe 3 into the first piping system 4, which is made up of a number of tubes, all constructed alike, provided with interior packing of uniform resistance 5, and surrounded by a water jacket 6. The circulation of the water can be regulated by means of the admission valve 7. Each tube can be isolated from the rest of the apparatus by means of the dampers 8 and 9. The gases then pass through the rest of the tubes 10, which are constructed in a similar

FIG. 33. DIAGRAM OF KALTENBACH PIPE PROCESS FOR THE MANUFACTURE OF SULPHURIC ACID

fashion, and finally through the Gay-Lussac tower 11, which may itself constitute the last pipe system of the series, the only difference being that the temperature is maintained therein at as low a point as possible.

"The nitro-sulphuric acid (60 deg. Bé.) recovered from the Gay-Lussac tower in the reservoir 12 is raised by means of the pump 13 to the supply tank 14, which feeds the Glover tower. The acid which comes from the tower and is collected in the tank 15, after having first passed through the cooler 16, is partly returned to the Gay-Lussac feed tank 18 by means of pump 17. The surplus acid is removed through the pipe 19 and forms part of the production.

"The pipe systems 4 and 10 are supplied with acid by means of the feed tanks 20, which may receive a regulated quantity of acid through the piping arrangement

*For Parts I, II and III, see CHEM. & MET. ENG., vol. 25, Nos. 19, 20 and 21, pp. 861, 917 and 964.

¹⁶*Chimie et Industrie*, vol. 3, No. 4, 1920; abstracted by Ismar Ginsberg in *Chemical Age*, vol. 28, p. 295.

21, which conveys the acid recovered in the corresponding system of tubes. The acid is collected in the reservoir 22, and is elevated by the corresponding pump 23 (1) through the pipes 24, connected to the line supply of nitro-sulphuric acid used in irrigating the Glover tower; (2) through the pipes 25, conveying the 60 deg. Bé. sulphuric acid used in irrigating the Gay-Lussac tower; (3) through the pipes 26, connected with the water supply; and (4) through the pipes 27, conveying acid from the catch-tank 22 of the same pipe system. This latter acid from the lower catch-tanks 22 can be cooled by means of an appropriate cooling system. The tanks are provided with outlet pipes, making it possible to remove acid which would correspond to any piping system in the series."

It will be observed that this process not merely tries to eliminate the heat of reaction by a more or less intense external cooling, which is claimed to be twenty times as effective as the cooling effect of air-cooled lead chambers, but that it also combines with that effort the practice used in the tower processes (such as the Opl and the packed cell processes), of circulating cooled acid through packed spaces, in counter-current to the flow of gases.

The advantages claimed for this process are:

1. Great ease of controlling the reaction temperature, by means of the circulation of water in the water jackets, and of cooled acid within the tubes.
2. Effective utilization of the surface of the tubes for the interchange of heat.
3. Reduction in the amount of lead and other materials of construction used, thus reducing first cost.
4. Ease of isolating one or more tubes for cleaning or repairing, without affecting rest of plant.
5. Possibility of limiting the number of tubes used to precisely what is needed for production required.
6. Complete independence of atmospheric conditions.
7. Less difficulty in concentrating the entire production to 60 deg. Bé. by making use of the heat generated in the reactions.
8. Elimination of water-atomizing apparatus.

It is apparent that such an apparatus as this is much more complicated, so far as construction details are concerned, than either a chamber plant or a tower plant. Announcement has been made that an installation of commercial size has been erected. Information as to details of construction, operating results, and durability of the apparatus in service will be awaited with interest.

"PACKED CELL" PROCESS

The "packed cell" process, described briefly in U. S. Bureau of Mines Bulletin No. 184,¹⁷ is the invention of E. L. Larison, of the Anaconda Copper Mining Co., Anaconda, Mont. The process is protected by U. S. Patent 1,342,024, issued June 1, 1920. Another patent, U. S. 1,334,384, covers special features of tower construction, designed by Larison.

The packed cell process is a nitration process, and in its use of acid-sprayed packed towers, or "cells," instead of lead chambers, for the reaction spaces it resembles more the European Opl process than any other. For the operation of the process a specially designed "packed cell plant" was needed.

In designing a type of plant which would give promise of being less costly, less bulky and more efficient than

the conventional chamber plant, two desirable features of operation were kept in mind, together with the idea of adapting to these features a recent development in chemical tower construction, previously referred to.¹⁸ These three ideas were: First, to construct an apparatus in such a way that the gas mixture from the Glover tower would be made to impinge vigorously on surfaces wet with sulphuric acid of specific gravity too low to effect appreciable absorption of oxides of nitrogen; second, to control the temperature of the reacting gases by circulating in direct contact with them quantities of cool weak acid; third, having provided for the removal of the reaction heat by means other than by radiation through metallic walls, to dispense altogether with lead chambers and adapt acid-proof masonry towers (now at a satisfactory stage of development), internally packed, to the new design.

These considerations led to a design of plant including essentially the following: (1) A Glover tower of

FIG. 34. PLAN OF ANACONDA PACKED CELL ACID PLANT. CAPACITY 21 TONS OF 60 DEG. BE. ACID PER DAY

conventional design. (2) A series of packed cells, or towers, built *en bloc*, exterior walls as well as interior walls of acid-proof masonry, the whole structure built in a lead pan, and the towers packed with checkerwork brick; the gas to take an alternately downward and upward course in passing through the cells; and each cell provided on the top with acid-distributing apparatus. (3) Gay-Lussac towers built *en bloc*, but as a separate structure from the packed cells. Construction similar to that of the latter structure, with the exception of provision of a gas downtake, unpacked, between Gay-Lussacs.

After experimenting on a small scale with this process, a plant of about 20 to 25 tons capacity was built at Anaconda. The plant consisted of one Glover tower, five packed cells in series and two Gay-Lussac towers, and is shown in plan and elevation in Figs. 34 and 35. Referred to the total packed cell space, the packed Glover space was about 15 per cent, and the packed Gay-Lussac space was about 60 per cent. At this plant the packed cell and Gay-Lussac structures were sheathed with 6-lb. lead. After the operating conditions were established, part of the lead sheathing was removed to determine whether acid or gas leakage through the acid-proof masonry was serious. It was found that gas leakage was negligible and acid leakage was slight. As the acid leakage made the wall wet, a 4-in. veneer wall was laid 2 in. away from the main wall and tied into the latter at suitable intervals with brick. This, it is said, made a gas-tight wall and a dry, clean outside.

The gas, derived from roasting copper concentrates,

¹⁷Wells and Fogg, "The Manufacture of Sulphuric Acid in the United States," pp. 111-114 (1920).

¹⁸See Part II, CHEM. & MET. ENG., vol. 25, No. 20, p. 917.

was forced into the acid plant by a Buffalo Forge Co. volume blower, with cast-iron housing, plate runner and water-cooled bearings, which was located between the burners and the Glover tower. For pumping the acids, direct-connected motor-driven vertical centrifugal pumps were installed, iron ones for 60 deg. acid and lead or lead protected pumps for weaker acid. Coolers of conventional design were provided for cooling the Glover acid and the cell acids; and provision was made for introducing warm acid into the later cells and cold acid into the earlier cells, with a view to maintaining favorable reaction temperatures throughout. The final cell of the series of five, however, was fed with generous quantities of cold acid, in order to cool the gas mixture prior to entry into the first Gay-Lussac tower. For hydration, neither steam jets nor water atomizers were used; but water, added to the circulating cell acids in the proportions required, was introduced into the acid-distributing boxes at the tops of the cells.

This plant was first operated in May, 1919. Operating on a rather irregular roaster gas, the actual acid production, over a period of several months, is stated to have been at the rate of (nearly) 4 lb. of 60-deg. acid per cu.ft. of packed cell space; or, in other words, 1 cu.ft. of gross packed cell space was employed per lb. of sulphur recovered as acid.

The actual capacity of the plant is given as 21 tons of 60-deg. acid per day.

In order to produce sulphuric acid in as small a reaction space as 1 cu.ft. per lb. sulphur per day, it was

FIG. 35. ELEVATION OF ANACONDA PACKED CELL ACID PLANT

necessary, as had been expected, to increase greatly the concentration of nitrogen oxides in the gas mixture within the reaction spaces provided. The proportion of nitrogen oxides usually carried in circulation in the gas of a chamber plant, operating at the rate of 8 or 10 cu.ft. of chamber space, expressed in terms of nitrate of soda, is from 21 to 25 parts of nitrate of soda per 100 parts of sulphur. In the packed cell process the total amount of nitrogen oxides in circulation, expressed in the same terms, was about 70 parts of nitrate of soda per 100 parts of sulphur, or about three times the usual concentration. This feature of making sulphuric acid from a gas mixture containing oxides of nitrogen and oxides of sulphur in the proportion derived from not less than $\frac{1}{2}$ lb. of sodium nitrate per lb. of sulphur (a 50 : 100 ratio) appears prominently in Larison's patent claims. As compared with a chamber plant operating at the average rate of 10 cu.ft. of space per lb. of sulphur per day, the packed cell plant made acid, accord-

ing to the figures given, at an increase in reaction speed of 900 per cent. Just how much of this increase is attributable to the increase in concentration of nitrogen oxides in the gas mixture and how much is due to more vigorous impingement of the gases on the surfaces of the cell packing is not definitely known; but if we assume that the reaction velocity increases directly with the concentration of nitrogen oxides in the gases, the reaction space required per lb. of sulphur per 24 hours was reduced to 3.33 cu.ft. by increasing the niter concentration; and impingement of the gases on the cell packing was perhaps accountable for the further increase in reaction velocity, referred to the latter space (3.33 cu.ft.), of 2.33 per cent, bringing the required cell space down to 1 cu.ft. per lb. sulphur per 24 hours.

Wells and Fogg state¹⁹ that the niter consumption at this plant at the start of operations was 6 per cent, referred, presumably, to sulphur in acid made. Later advices give the niter consumption as 4.8 per cent on sulphur in acid made, and tests made on the Gay-Lussac exit gases indicate that with additional Gay-Lussac space the niter consumption might be brought down to a little under 4.0 per cent. The nitrosity of the nitrous vitriol is carried at 70 to 80 oz. NaNO_2 per cu.ft.

The optimum temperature of the acid fed into the several cells is not given, as it is stated to be variable with varying conditions. The quantity of water required for cooling the acids is given as about 2,500 gal. per ton of 60-deg. acid produced.

The gas pressure at the exit of the hot gas blower is carried at about 1.2 in. of water. No figures are available as to the power required to drive the gas through the resistance offered by the packing of the packed cells, as compared with the power required for moving gases at a chamber plant. The power used for pumps and fans combined amounts to about 2 hp. per ton of 60-deg. acid.

The quantity of acid circulated over the Gay-Lussac towers amounts to about 300 per cent of the daily production in terms of 60-deg. Bé. acid. The quantity of acid introduced into the packed cells amounts to about 10 tons of 50-deg. Bé. acid per ton 60-deg. Bé. acid.

The advantages claimed for this type of plant are a saving of 40 to 50 per cent in first cost, and a saving of 80 per cent in ground space. The Anaconda plant is not yet old enough to permit of giving figures as to maintenance expense; it is believed by the designer, however, that over a period of years both operating and maintenance costs will be somewhat lower than at the ordinary chamber plant.

SILICA GEL

Silica gel, prepared by treating a solution of silicate of soda, under special conditions, with dilute hydrochloric or sulphuric acid, followed by coagulation, drying, washing and partial dehydration, is an agent which has been proposed for a variety of uses in the sulphuric-acid industry.

The method of making silica gel is the invention of W. A. Patrick of Baltimore, Md., and is protected by U. S. Patent 1,297,724. A patent covering a method and apparatus for the separation of vapors and gases by means of silica gel (U. S. 1,335,348) has been issued to W. A. Patrick, B. F. Lovelace and E. B. Miller. Basic facts and observations relative to the adsorption of vapors and gases by silica gel, with special reference

¹⁹Op. cit., p. 112.

to the adsorption of sulphur dioxide, have been published by E. B. Miller in a paper presented before the American Institute of Chemical Engineers in 1920.²⁰

Silica gel is prepared under carefully standardized conditions, and when dried and "activated" by passing through it for 2 hours air heated to 125 to 150 deg. C. it has a moisture content of 5 to 7 per cent. It is a semi-transparent, glassy, brittle, highly porous solid.

Miller's paper describes and illustrates several types of bed absorbers, wherein gases or vapors may be adsorbed in granular gel; and also refers briefly to a pulverized-gel absorber, whereby the activated gel, ground to from 80 to 200 mesh, is fed into the stream of gas to be adsorbed, which escapes through a dust filter, and the adsorption takes place in the gas conduit and in the filter bags. The dust is shaken from the bags into a regenerator, in which by means of heat the adsorbed gas is recovered, and simultaneously the gel-dust is reactivated for use again.

Thus far the only practical application of silica gel to industrial use on a commercial scale has been for the adsorption of gasoline vapor in oil-refining processes, but the same type of apparatus is said to be adapted to the recovery of a variety of industrial gases. For some time the Davison Chemical Co., which holds the patent rights, has been experimenting with various propositions for using silica gel in the sulphuric-acid processes.

USES FOR SILICA GEL IN SULPHURIC-ACID INDUSTRY

Some of the ways in which it has been proposed to use silica gel for effecting economies in the manufacture of sulphuric acid are the following:

1. The adsorption of sulphur dioxide from gas mixtures containing only a small percentage of that gas, followed by the recovery of the sulphur dioxide from the gel, for the purpose of producing a gas mixture strong in sulphur dioxide. By this means it is stated that a gas mixture containing, for example, one-half per cent SO_2 , can be used for producing a gas mixture containing 8 per cent SO_2 or more.

Experiments have shown that the gel is capable of adsorbing, from a gas mixture containing 8.75 per cent SO_2 , 6.8 per cent of its weight of sulphur dioxide, at a mean temperature of 40 deg. C. Less concentrated gases are less efficiently adsorbed. For further data the reader is referred to Part I of Miller's article.²¹

2. The adsorption in silica gel of the SO_2 in the gas mixture of a chamber plant, after passage through only the first half of the chambers, and the recovery of the adsorbed SO_2 , to make a gas mixture strong in SO_2 to reintroduce into the first chamber. It is a well-known fact that the latter half of the chambers of a chamber plant do relatively little work, as compared with the first half, and by this means it is proposed to eliminate the inefficient latter half of the chamber space now employed, and cause all the oxidation and condensation to be done in the efficient first half.

3. The recovery of sulphur dioxide and nitrogen peroxide from the gas mixture escaping from the Gay-Lussac tower. Also the indirect recovery of nitric oxide from the same source, by oxidizing the latter to nitrogen peroxide, with subsequent adsorption in silica gel. The extent to which nitrogen peroxide in the gas mixture escaping from the Gay-Lussac tower can be adsorbed in a practical way in silica gel is now being

determined experimentally at the plant of the Davison Chemical Co.

4. The recovery of sulphur dioxide and nitrogen peroxide from the gas mixture issuing from the last chamber of a chamber plant as a substitute for the Gay-Lussac tower, thus eliminating the latter.

5. The conversion of SO_2 to SO_3 catalytically, by passing the gas through gel previously treated with special catalyzing agents, such as certain metallic salts. By means of platinized silica gel, such a conversion has been obtained experimentally. Experiments on the catalytic efficiency of a variety of metallic salts adsorbed into the pores of silica gel have been in progress for some time at the Davison laboratories. It seems premature at present to make any very definite claims for the future of metalized silica gel as a catalytic agent on a commercial scale.

CONCLUSION

In reviewing this series of articles it will be noted that the following recent developments in the sulphuric-acid industry have been considered:

1. A variety of new kinds of plant equipment, such as electrically driven acid pumps, acid valves and gas blowers of various designs and materials, and electrical apparatus for the precipitation of dust, all of which have been put on the market with a view to supplanting established equipment used for the corresponding purposes, considered to be less efficient, less durable or more expensive than the new.

2. All-Masonry Gay-Lussac and Glover towers, interchamber towers and a new type of sulphuric acid chamber, water-cooled on its outside.

3. Two proposed types of nitration processes, which dispense with lead chambers altogether.

4. A remarkably porous solid, having peculiar adsorption properties, including the quality of being able to adsorb into its pores metallic salts in such a finely divided condition as to effect catalytic oxidation of sulphur dioxide, but whose development, as a catalytic agent, has not yet emerged from the embryonic stage.

The salient points of each kind of plant, or of plant equipment, have been briefly described in such a way that the reader may compare them and that those who have to build or equip sulphuric-acid plants may be assisted in making their choice.

ACKNOWLEDGMENTS

For information, photographs and drawings used in the preparation of this series of papers the author is indebted to the following gentlemen: Peter S. Gilchrist, president, Chemical Construction Co.; J. N. Houser, manager, Tennessee Copper Co.; E. L. Larison, superintendent acid department, Anaconda Copper Mining Co.; E. B. Miller, vice-president, Davison Chemical Co.

For furnishing illustrations and detailed information relative to recent developments in sulphuric-acid plant equipment the author wishes to express his thanks to the following business houses: Chemical Equipment Co., Chicago, Ill.; Chemical Pump & Valve Co., Perth Amboy, N. J.; Duriron Co., Dayton, Ohio; Charles S. Lewis & Co., St. Louis, Mo.; Monarch Manufacturing Works, Philadelphia, Pa.; Packards & James Fison (Thetford), Ltd., Ipswich, England; Research Corporation, New York, N. Y.; Schutte & Koerting Co., Philadelphia, Pa. Other acknowledgments have been indicated at appropriate places in the text, and in footnotes. Atlanta, Ga.

Heat-Treatment of Brass and Brasses Containing Tin*

Brasses Containing a Little Beta Respond to Heat-Treatment—Tin-Brasses, Developing a Special Constituent Analogous to Delta in Bronzes, May Have Their Physical Properties Changed Very Notably by Proper Annealing and Quenching

BY LÉON GUILLET

IT IS known that certain industrial alloys of copper and zinc may be hardened by quenching. Under the microscope these alloys show both the α and β constituent, or if formed of pure alpha are practically saturated in zinc. Industry has not yet made use of this heat-treatment, no doubt because the most of those who use the metal completely ignore this property, and perhaps also because the hardening action is not very pronounced.

A systematic study has been made upon special brasses, which has led the author to form the general conception of the coefficient of equivalence.¹ Further

FIG. 1. EQUILIBRIUM DIAGRAM FOR COPPER : ZINC ALLOYS

After Gulliver, "Metallic Alloys," p. 267.

investigations on the influence of the different elements upon the properties of the heat-treated alloys should be useful, especially if the determinations are based upon an exact knowledge of the position of the transformation points. Attention has been attracted to brasses containing tin, for the following important reason:

The tin-brasses contain a special constituent which bears a strange resemblance to the delta constituent of bronzes (a solid solution very closely corresponding to the compound Cu_3Sn). This constituent is accompanied by hardness and brittleness; it injures the mechanical qualities of the alloy, especially when present in sufficient amount. Heat-treatment does not cause the disappearance of this constituent, and therefore does not materially improve the properties of the tin-brasses.

Quenching has a strong influence upon the structure of copper: zinc alloys which forecasts the equilibrium diagram, when taking into account the fact that the

eutectoid is not resolved—a veritable troostite is found instead.

Brasses formed of α plus β solutions,² quenched from above 475 deg. C., have their content in α diminished, whereas the constituent that reminds one of troostite becomes more apparent; nevertheless, this constituent is less readily etched, and is present in a polyhedral form. No doubt quenching prevents the separation of the constituents of this metal, as seems to be indicated by its easy coloration, and the constituent thus obtained can be better compared to the gamma iron in steels than to the troostite of the same alloys. This seems to be β solution as it exists at a high temperature. (See Fig. 2.)

When the temperature is increased the α solution almost completely disappears and pure β is approached. It has been noted, however, that in the interstices of the grain boundaries there are some traces of α plus β in a finely divided state; complete solution appears to be difficult, at least for brass rich in α solution.

On the other hand, the equilibrium diagram shows a line aa_1 (Fig. 1) separating the region of pure α from that of α plus β , which is a curve bent toward the Y axis. It follows that alloys containing 63 to 72 per cent of copper, when carried to a proper temperature, are no longer in the α zone, but cross into the zone where some β solution is formed. Cooling quickly from

²In industrial brasses this comprises those containing from 55 to 63 per cent copper, and also includes those containing the unresolved constituent frequently called "apparent beta."

FIGS. 2 AND 3. BRASSES QUENCHED IN WATER FROM 850 DEG. C. ETCHED WITH ANHYDROUS IRON PERCHLORIDE

Fig. 2. 60 : 40 brass, $\times 50$. Fig. 3. 65 : 35 brass, $\times 430$.

*From *Revue de Métallurgie*, July 1921, pp. 445-58.

¹"Ternary Brasses," *CHEM. & MET. ENG.*,

such temperature, the resulting alloy will be formed of these two constituents. (Fig. 3.) This is a very interesting hardening (by quenching) by simply heating the specimen through a line in the diagram not belonging directly to a eutectoid.³

A little of the β is clearly to be seen in this quenched alloy (Fig. 3). Quenching does not affect the mechanical properties to a great extent; no doubt this is due to the non-resolution of the eutectoid, leading to the supposition of a "semi-quenched" state existing as a matter of course in alloys formed of α and "apparent β "; the "apparent β " seems to be a veritable troostite replacing the eutectoid between α and γ solutions. Besides, quenching does not produce a martensitic structure in brass, at least as far as is known.

In Table I is presented a series of Brinell tests⁴ published in 1914 bearing on this subject.

TABLE I. HARDNESS OF QUENCHED BRASSES

Cu, per Cent	Annealed at 750 Deg. C.	Quenched in Water at					
		420 Deg. C.	520 Deg. C.	620 Deg. C.	720 Deg. C.	820 Deg. C.	850 Deg. C.
56	126	134	136	121	124	126	Broken
58	109	102	116	124	131	128	135
60	88	92	94	101	114	134	137
62	81	82	84	82	100	115	110
65	59	62	60	63	63	76	81
70	59	63	62	61	62	56	57

Recently the following Brinell hardness tests have been made on a brass having 55 per cent Cu and formed therefore of "apparent β ," sensibly pure:

Annealed state, 111.
Quenched at 650 after heating for 10 minutes, 119.
Quenched at 750 after heating for 10 minutes, 118.
Quenched at 850 after heating for 10 minutes, 118.

The following conclusions may be drawn:

1. Quenching increases the hardness of brasses; the increase sometimes reaches 30 Brinell units, more often it does not exceed 10. Finally, certain brasses are not appreciably hardened by quenching.
2. In brasses showing α plus apparent β under the microscope, the hardening upon quenching is a function of the amount of α constituent; brass formed wholly of apparent β is hardly affected by quenching.
3. The necessary quenching temperature to obtain the maximum hardness is proportionally higher as the amount of alpha increases, exactly as the diagram indicates.
4. Alpha brasses containing less than 70 per cent Cu harden slightly on quenching; a certain quantity of β is formed.
5. These facts conform to the equilibrium diagram; the existence of a "troostitic" structure in place of the eutectoid between α and β constituents indicates a "semi-hardened" condition in the unquenched products.

TABLE II. MECHANICAL PROPERTIES OF 60:40 BRASS

	Tension Tests				Impact Tests		Hardness
	Ultimate Strength	Elastic Limit	Elongation	Contraction	Resilience	Angle, Deg.	
Rolled.....	54,000	17,100	48.0	51.7	14.3	110	93
Annealed at 800 deg. C....	52,000	14,600	50.0	62.2	17.5	110	78
Quenched at 600 deg. C.	51,500	?	36.0	52.7	13.3	139	92
in water.....							
Quenched at 800 deg. C.	53,000	33,100	8.0	11.5	7.8	153	145
in water.....							

Table II shows the mechanical properties of the alloy Cu 60.15, Zn 39.84, Sn 0, Fe and Pb traces.

There is a discrepancy between the hardness and the

tension tests after quenching at 800 deg. C. This must be attributed to overheating, since the fracture showed a coarse grain.

COMPOSITION OF THE TIN-BRASSES

For this investigation ingots cast with square lugs were used, a form which the author has described many times.⁵ The lugs are used for the tests on the cast metal, and the center of the ingot is to be rolled hot. All of the ingots had square lugs, 25 mm. on a side attached to a central round of 100 mm. diameter, 250 mm. long. A series of very pure alloys were made. Their analyses are given in Table III.

TABLE III. ANALYSES OF TIN-BRASSES (FIRST SERIES)

No.	Cu	Zn	Sn	Fe	Pb	Total
1	60.15	39.84	0.00	Traces	Traces	99.99
2	60.52	39.31	0.16	Traces	Traces	99.99
3	60.25	39.19	0.52	Traces	Traces	99.96
4	60.41	38.79	0.78	Traces	Traces	99.98
5	60.46	38.67	0.85	Traces	Traces	99.98
6	60.64	38.32	1.02	Traces	Traces	99.98
7	60.50	38.26	1.23	Traces	Traces	99.99
8	61.57	35.33	3.01	Traces	Traces	99.91
9	61.12	33.86	4.89	Traces	Traces	99.87

On the whole, in this series the amount of copper remained between 60.1 and 60.6, the tin increased from 0 to 5 per cent.

In addition three specimens were examined containing a larger amount of copper, and some others, much less pure industrial products, containing some lead and an increasing amount of tin. The analyses are given in Tables IV and V.

TABLE IV. PURE ALLOYS; HIGH COPPER (SECOND SERIES)

No.	Cu	Zn	Sn	Fe	Pb	Total
10	67.61	30.84	1.60	Traces	Traces	100.05
11	80.59	17.85	1.57	Traces	Traces	100.23
12	80.23	16.47	3.15	Traces	Traces	99.85

TABLE V. IMPURE INDUSTRIAL ALLOYS (THIRD SERIES)

No.	Cu	Zn	Sn	Fe	Pb
13	59.38	37.90	0.00	0.69	1.88
14	58.80	38.25	0.63	0.52	1.70
15	59.13	37.45	1.12	0.44	1.78
16	58.98	37.65	0.31	0.48	2.74
17	59.12	36.83	0.76	0.67	2.58
18	58.90	36.65	1.18	0.53	2.72

The studies have included (1) micrographic examination; (2) determination of transformation points; (3) mechanical tests in the cast state for the first and second series; mechanical tests in rolled, drawn and annealed state for the first and third series, with the exception of the 3 and 5 per cent tin alloys; mechanical tests on all alloys, in the quenched condition.

All ingots except 8 to 12 inclusive were rolled to 22-mm. round bars, and then drawn to 20 mm. diameter. Annealing was done at 800 deg. C. in oxide of iron (in order to avoid that loss by volatilization in a reducing atmosphere indicated in researches made in collaboration with M. Ballay). This relatively high temperature was adopted to secure greater homogeneity.

Quenching was done in water after heating 15 minutes at 600 or at 800 deg. C.

DETERMINATION OF CRITICAL POINTS

Critical points were determined with a Saladin-Le Chatelier double galvanometer; the comparison specimen was copper; temperature reached in the heating was from 800 to 850 deg. C.; heating time was 1 hour 15 minutes; cooling required 1 hour 30 minutes to pass

³This seems also to be the case with duralumin.

⁴Revue de Métallurgie, Memoirs, 1914, p. 1128.

⁵Revue de Métallurgie, Memoirs, 1906, p. 247.

TABLE VI. THERMAL ANALYSIS OF ALLOYS				
No.	Amount in		Transformation Points	
	Cu	Sn	Heating	Cooling
1	60.15	0.0	456, 750	705, 445
2	60.52	0.16	445, 760	720, 445
3	60.25	0.52	445, 740	690, 445
4	60.41	0.78	445, 745	700, 445
5	60.45	0.85	445, 740	700, 440
6	60.64	1.02	445, 480, 740	690, 445
7	60.5	1.23	445, 490, 730	680, 440
8	61.57	3.01	500, 760	720, 500
9	61.12	4.89	530, 710	630, 520

11	80.59	1.57		
12	80.23	3.15		

from 850 to 200 deg. C. The results obtained are given in Table VI. *Italic figures indicate abnormal points*—that is to say, those which are not found in tin-free brasses. Fig. 4 reproduces some of the curves obtained.

FIG. 4. HEATING AND COOLING CURVES
a, alloy 7; b, alloy 8; c, alloy 9; d, alloy 10.

These determinations lead to the following conclusions:

- 1. The first five specimens containing 60 per cent Cu and up to 0.85 per cent Sn possess no other transformation points than do normal brasses.
- 2. Alloys with 60 per cent Cu and 1 to 1.3 per cent Sn (Nos. 6 and 7) absorb a small amount of heat at 480 to 490 deg. C.; this thermal anomaly was not met in cooling; its disappearance may be attributed to the slowness of the operation. If the determination is repeated, the transformation reappears at each heating;

FIGS. 7 AND 8. DELTA CONSTITUENT IN EUTECTOID
IN HIGH-TIN BRASSES. $\times 200$
Fig. 7. Cu 67.6, Sn 1.50. Fig. 8. Cu 61.6, Sn 3.05.

it is not due, therefore, to the heterogeneity of the specimen.

- 3. The alloys containing 60 per cent Cu with 3 to 5 per cent Sn present two points, due to the presence of tin, since the micrographic examination shows that these products do not contain apparent β . It will be shown that these points correspond to the beginning and the end of solution of the special constituent. Furthermore, the anomalies increase as the tin increases.
- 4. As copper increases, the amount of tin necessary to induce unusual transformation points also increases; thus none were found in an alloy containing 80 per cent copper and 3 per cent tin.

MICROGRAPHS OF CAST OR ANNEALED SAMPLES

Microscopic observations made after etching with acid iron perchloride may be summarized as follows: Alloys 1 to 4 are formed of the α and β constituents

FIGS. 5 AND 6
Fig. 5. Cast brass; Cu 60.46, Sn 0.85; white is beta, gray is alpha constituent, rim is special delta constituent due to tin. $\times 430$.
Fig. 6. Annealed brass; Cu 60.50, Sn 1.23. $\times 430$.

FIGS. 9 AND 10. QUENCHED TIN-BRASSES. $\times 200$
Fig. 9. Cu 60.64, Sn 1.02; quenched from 600 deg. C.
Fig. 10. Cu 67.6, Sn 1.5; quenched from 650 deg. C.

of ordinary brass; the amount of α is a little less than that found in tin-free alloys having the same amount of copper. This is true for cast metal as well as after annealing at 800 deg. C., and confirms what the author has already written on this subject.⁶ The value of the coefficient of equivalence of tin is about 2.

On the other hand, the following phenomenon may be noted very clearly: Constituent β is attacked by the etching reagent with much more difficulty as the tin increases, so that after a prolonged attack the reagent may cause the β to appear white against a colored ground mass of α . This is perhaps one reason why tin-bearing brasses have been successfully used on account of their resistance to corrosion. Fig. 5 shows this fact for alloy 5 (0.85 per cent Sn). The same alloy, as cast, shows a little of the special constituent, located at the edge of the white β region. Polishing in low relief also shows this clearly.

⁶*Revue de Métallurgie, Memoirs*, 1906, p. 264: "Ternary Brasses," CHEM. & MET. ENG., vol. 24, p. 177, Jan. 26, 1921.

Annealing at 800 deg. C. for 2 hours causes this small quantity of special constituent to disappear; it may be designated by the letter δ .

When the amount of tin reaches 1 per cent, the constituent exists in the annealed metal as well as in the metal as cast (Fig. 6), and its proportion increases with tin, so that brasses 8 and 9, with 3 and 5 per cent Sn respectively (Figs. 7 and 8), have the same appearance as bearing bronzes.

Examination of brass containing more than 60 per cent Cu shows that as the amount of zinc decreases a greater quantity of tin may enter into solution in the α constituent. For instance, with 67 per cent Cu, the amount of δ constituent is very slight for 3.6 per cent Sn; it is zero with 80 per cent Cu and 3 per cent Sn.

Absolute agreement should be noted between the appearance of the special constituent and the transformation on heating at about 480 deg. C., at least for alloys with more than 1 per cent Sn.

Tin-brasses not showing the special δ constituent,

FIGS. 11 TO 16. PHYSICAL PROPERTIES OF TIN-BRASSES. ALLOYS 1 TO 7

Fig. 11. Physical properties of cast tin-brass containing 60 per cent Cu.

Fig. 13. Physical properties of cast tin-brass, quenched at 600 deg. C. (60 per cent Cu).

Fig. 15. Physical properties of drawn tin-brass containing 60 per cent Cu.

Fig. 12. Physical properties of tin-brass rolled and quenched at 600 deg. C. (60 per cent Cu).

Fig. 14. Physical properties of rolled tin-brass (60 per cent Cu), quenched at 800 deg. C.

Fig. 16. Physical properties of rolled and annealed tin-brass (60 per cent Cu).

when quenched, appear as ordinary brass. If it contains some δ this special constituent goes into solution at elevated temperatures, and after quenching at 600 deg. C. has disappeared. This is well shown in the photomicrographs, Figs. 9 and 10.

After quenching from 800 deg. C. there is a recurrence of a little α plus β at the boundaries of the α grains, as has already been remarked. But if alloys containing a large amount of tin such as shown in Figs. 7 and 8 are examined after quenching at 650 deg. C., it will be seen that the eutectoid has disappeared, δ having gone into solution, leaving only a white uniform constituent. Brass with 67.6 per cent Cu and 1.5 per cent Sn shows this phenomenon very clearly in Fig. 10; there is a little δ in the annealed metal, but after quenching at 650 deg. C., a white region may be observed, replacing the former eutectoid.

In conclusion it may be affirmed that the δ constituent is due to the presence of tin, and even if not identical it is allied to the δ constituent of bronzes. Both disappear after quenching under the same conditions.

MECHANICAL TESTS

All the results of mechanical tests are collected in Table VII, where the history of the test-pieces is briefly noted. Tension tests were performed upon a test-piece with diameter of 13.8 mm., 100 mm. in length. An autographic Amsler machine was used at a velocity of 1 mm. in 10 seconds. Impact tests were made with a rotating hammer, having a velocity at impact of 8.6 m. Test pieces were of the Mesnager type, 10 x 10 mm., notched 2 x 2 mm. with round bottom. Brinell hardness was tested by 20 seconds' loading.

Results obtained upon the pure alloys are assembled

in a series of curves, Figs. 11 to 16 inclusive, each graph representing a given physical condition.

From the curves and tables some interesting general conclusions may be drawn:

1. In rolled and annealed samples (Fig. 16), tin increases the ultimate strength slightly up to 0.8 per cent; affects the elastic limit but slightly; reduces the elongation, reduction of area and resilience, especially above 0.8 per cent Sn; and increases the hardness a little without making the alloys less readily machined or punched. The latter conclusion is at variance with common report, but is in conformity with the author's previous investigations.

2. Quenching the rolled bars at 800 deg. C. greatly increases the hardness (Fig. 14), but gives very bad results as to ductility and resilience.

3. Quenching at 600 deg. very slightly hardens brass formed of α and β without the δ constituent. The alloys containing the latter are improved in a truly remarkable manner, as is shown by the figures obtained with all alloys containing at least 1 per cent of tin. Graphs 11 and 13 should be compared. It will be seen that the average ultimate strength is increased from 50,000 to 64,000 lb. per square inch, the elastic limit from 17,000 to 28,400 lb. per square inch, the reduction of area from 40 to 60, the resilience from 12 to 16 and the hardness from 95 to 105. Such improvement is even more clearly marked in industrial alloys, especially alloy 18.

4. Alloy 10, containing 67 per cent copper, is not improved by quenching from 650 deg. C.; a white constituent still persists in the microstructure.

5. Comparing rolled and drawn products in Table VII and Fig. 15 to Figs. 12 and 14, it will be seen that cold work and quenching produces entirely different changes in the physical properties.

6. Finally, comparing alloy 1, containing no tin, and alloy 7, containing considerable tin, it is immediately apparent that the added element has a profound effect on the results obtained after heat-treatment.

CONCLUSIONS

First, these investigations emphasize that the part played by tin in brasses is not as injurious to the mechanical properties as is generally thought, at least when it does not exceed 1 per cent.

Next, attention is called to the remarkable action of quenching, which suppresses a hard and brittle constituent (very closely related to the δ constituent of the bronzes, if not identical with it) and considerably improves all the qualities revealed by mechanical tests.

Third, brasses with 60 per cent Cu containing 1 to 2 per cent of tin are less notable in the drawn or rolled state, apart from their known non-corrosive property, but they are very interesting in the quenched state.

Location of Electric Power Stations Shown on New Series of Maps

Manufacturers interested in the location of plants within reach of electric power will welcome the series of maps now in preparation by the United States Geological Survey, showing the location of power stations and electrical transmission lines used by public utilities.

The first of the series is a map of New York State, 64 in. long and 45 in. wide, scale 1 : 500,000, copies of which may be obtained for \$1 each from the Director, United States Geological Survey, Washington.

Reforestation of France

Before the war France possessed approximately 185,000,000 acres of productive forests. The bulk of these forests, about 177,000,000 acres, was in private ownership, while 3,000,000 acres was owned by the state, and 5,000,000 acres by the communes.

The war wrought great havoc with the French forests. Large areas were totally destroyed through fire, while the forests back of the fire zone were heavily drawn upon for firewood, trench timber and other necessities. After the armistice the Water and Forest Board of France, which is the national body clothed with authority over the forests and international waterways, took up the problem of reforestation. The authorities admit, however, that given the most favorable developments, it will take at least a century to bring France's forests back to their condition in 1914.

A survey after the armistice showed that in the territory occupied by the enemy 300,000 acres of state forests, 322,500 acres of parish forests and 922,000 acres of privately owned forests were subject to devastation. In over one-third of this territory the productive capacity of the forests was completely destroyed. Over half a million acres must be refitted and rewooded to make it of any use. Another area of 375,000 acres shows the effects of abusive, premeditatedly destructive or wasteful fellings.

The Water and Forest Board has established a special forest reconstitution service. In each department which suffered from the invasion there has been set up a so-called "Forest Reconstruction Inspection," with definite duties relating to the restoration of the forests.

Corrosive Action of Soil on Pipes to Be Studied

The Bureau of Standards has recently undertaken an extensive investigation of the corrosive action of soil on pipes used for gas and water mains and services. In this investigation the bureau has the co-operation of the Bureau of Soils of the Department of Agriculture, the pipe manufacturers and the public utilities through the Research Sub-Committee of the American Committee on Electrolysis. Forty locations have been selected as representative of the principal families of soils to be found throughout the United States and in them will be buried a number of samples of every kind of iron and steel pipe in commercial use. Some of the samples will be uncovered and examined from time to time to determine the rate of corrosion.

Complete data on the physical and chemical properties of the soil will be obtained, also the chemical analyses of the pipe, their microstructure and complete metallurgical heating will be determined. Extensive laboratory experiments will be conducted to determine the effects of variations in individual characteristics of both soils and pipe materials. Some tests of representative pipe coatings will also be undertaken.

The results of the tests should be of great value in determining the importance of soil corrosion and in selecting the kind of pipe best suited for use in any particular soil.

It is expected that a good deal of data as to the relative rates of corrosion of different kinds of pipes in the soils under observation will be obtained within two or three years, but the experiment will probably continue over a period of eight or ten years.

Progress reports will be published from time to time as developments warrant.

Uses for Industrial Enameled Equipment*

Nature of the Field—Properties of Enameled Linings Compared With Metals—Industries Preparing Food Products Are Large Users—Chemical and Pharmaceutical Manufacturers Employ Glass-Lined Apparatus—Considerable Work Ahead in Developing New Applications in Industry

BY MAX DONAUER

Chemical Engineer, Elyria Enameled Products Co., Elyria, Ohio

ENAMELED apparatus has long ago proved its usefulness, but the field of its possibilities is far from being fully explored. Indeed, each new problem solved points to another opportunity still more interesting. And since every achievement invites another, perhaps a review of some of the fields of industrial enameled equipment may point to newer and still greater possibilities.

Types of Equipment.—Glass-enameled units for manufacturing purposes may range in size from 25 gal. to 7,500 gal., 100 gal. to 1,000 gal. covering the average limits of variation. The weight of materials handled and also the problems involved in processing them demand apparatus of rugged construction, enamel lined on the inside only. Manufacturing processes usually are planned for continuous operation of one kind, which must be carried out as economically as possible. These conditions require building and perfecting apparatus for many varied types of industrial processes.

Enameled units may therefore be fundamentally alike and yet have certain variations which make each adaptable for only one purpose. With kitchenware, lamp fixtures and similar articles, this may not be the case, but the enamel lining is an important feature whatever the actual application.

Classes of Use.—In spite of the varied requirements which manufacturing processes demand, enameled apparatus may be advantageously grouped, according to use, into three general classes, depending on whether they are for food, pharmaceutical or chemical purposes: For food work perhaps sanitation is paramount; for pharmaceutical preparations probably freedom from contamination, and for chemical uses possibly acid resistance is the chief requirement. But the list of demands made in each case is much longer and it may be interesting to examine a little more closely the requirements of a manufacturer and whether or not enameled equipment meets them or has any advantages or disadvantages which might influence the user of industrial equipment.

Points Considered When Purchasing Equipment.—A commercial piece of apparatus is purchased as an investment, and as such is judged according to points similar to the following: (1) Cost—first cost and upkeep, (2) delivery, (3) life of equipment, (4) ease of repairing, (5) producing capacity, (6) operating requirements, (7) kind of labor required for operation, (8) value of the salvage, etc. How each particular type of equipment ranks according to such a list depends somewhat on the viewpoint of the purchaser. Suffice it to say the manufacture or repair of enameled apparatus is specialized work which can be done only at a factory equipped for that purpose. However, the completed unit

has a very long life, no upkeep and requires a minimum of labor for operation. An enameled unit occupies little floor space and yet has a large operating capacity. Such points as these and many similar facts prove that the use of enameled equipment is very economical.

Of all the things that a manufacturer prides himself upon, nothing ranks higher than the reputation of his product. He does everything to improve it and to produce a better product than his competitor. It is generally conceded that it is better to handle pure products in glass-lined rather than in metallic containers. The users of equipment know its advantages and shortcomings better than anyone else and their experience has pointed out interesting features concerning various types of equipment.

PROPERTIES OF ENAMELED EQUIPMENT

Fundamental Advantages of Enameled Equipment.—Enameled apparatus is easily cleaned and made sanitary. It presents a container with an inert and tasteless lining which does not discolor food products, nor is its own color changed. When cooling food products in enameled equipment, there are no adhering incrustations which cannot be easily removed. In metallic equipment these incrustations cannot be loosened without considerable scouring and if not removed become breeding places for bacteria. Enameled steel transmits heat more slowly than metals. While heating, this slowness can usually be overcome by a higher thermal head. The slower heat transmission, however, permits obtaining more uniform temperatures, and sometimes steam can be employed without local overheating under conditions in which metallic equipment requires the use of cumbersome methods of hot-water circulation. To hasten cooling is a more difficult problem. Cooled products introduced into enameled containers, however, can be stored at cold temperatures for considerable periods of time.

Comparison of Glass-Lined and Metallic Units.—There is also the problem of the presence of a metallic or a glass lining itself. All commercial metals and alloys such as aluminum, tin, copper, bronze and Monel metal are affected somewhat by weak organic acids. Some of the compounds formed when these metals

FIG. 1. ACTION OF MILK ON METALS

*Paper presented in abstract before the American Ceramic Society Annual Meeting, Columbus, Ohio, 1921.

FIG. 2. DISCOLORATION OF LIGHT GRAPE JUICE CONCENTRATION

dissolve have strong metallic flavors, while others are rather tasteless. But such metallic compounds all tend to break up emulsions, to coagulate or bleach coloring matter and increase decomposition tendencies. It is interesting to note in this connection that sour cream while being made into butter will remove the tin lining in a processing vat in one week, and it has almost as vigorous an action on copper. Grape juice during vacuum concentration removes silver plating from a copper vacuum pan in a month's time.

As indicating in a general way the tendency for metals to corrode in contact with milk, Fig. 1 is shown.

FIG. 3. DISCOLORATION OF COTTONSEED OIL ON HEATING

Order of tubes, left to right: Unmarked, E-1, C-1, S-1, E-2, C-2, S-2, E-3, C-3, S-3

The upper row of strips shows various metals which had not been immersed in milk, while the lower row shows strips of the same metals which have been immersed in milk at pasteurizing temperature for 24 hours. Of particular interest is the fact that the first metal, aluminum, did not materially discolor but was nevertheless corroded. Monel metal discolored very definitely as did zinc. Tin discolored somewhat and was very definitely pitted.

Silver in contact with fruit juices turns black in a

FIG. 4. CARAMELIZATION OF SUGAR

few days. In fact, most metals turn black when used for processing foods unless they are continually scoured. Aluminum is very easily affected by weak organic acids. The products of corrosion have little taste, but their coagulating tendency and the bleaching effect during processing are well known. Copper is also acted upon by many compounds and the resulting products are exceedingly bitter. An average grade of pie filling when prepared in copper utensils dissolves enough copper to permit its being detected in the product by ordinary analytical methods.

As indicative of the action of metals in producing color variations in fruit juices, a series of concentrations of light grape juice has been made under varying

FIG. 5. BEVERAGE INSTALLATION

conditions and the change in color noted by comparison with standard caramel solution. The results are shown in Fig. 2. The heating conditions in curves 1 and 2 were identical, the evaporation in one case being carried out in a copper unit and in the other in an enameled unit. The same degree of concentration in an enameled unit under vacuum has resulted in a much less marked change in color, as will be noted in curve

FIG. 6. FRUIT JUICE TRANSPORTATION CAR

3. The dotted line at 0 indicates the original color of grape juice in terms of the standard caramel solution.

When iron equipment is used for refining oils, the product first prepared turns out dark yellow. Gradually the iron is covered with a crust of oxidized oil which lessens the discoloring. With enameled equipment, a glass lining, instead of a burned-on crust, is used to protect the oil. Oils do not form crusts on enamel. Similar differences are noted in other processes.

The tendency for vegetable oils to discolor when being heated in contact with metal is evident in Fig. 3, which

FIG. 7. JAM FILLING TANK

shows a series of tests on cottonseed oil under uniform conditions of heating, but in contact with enamel, copper and steel. The unmarked tube at the left indicates the intensity of color in the unheated oil. The oil in the tubes *E-1*, *C-1* and *S-1* were heated for a given time in contact with enamel, copper and steel. The oil in tubes *E-2*, *C-2* and *S-2* was heated for twice the period of time and that in tubes *E-3*, *C-3* and *S-3* for three times the period of time. It will be noted that in each case the change in color of the oil heated in contact with copper and steel is much more marked than that heated in contact with enamel. It should be noted that the differences in color intensity indicated in this figure are far from being as positive as in

FIG. 8. TOMATO PULP COOKER

the actual samples observed by the eye, due to the extreme difficulty of registering differences in intensity of yellow by means of the photographic plate.

There are other reasons for using enameled equipment which are advantages that are inherent to the glass lining itself. Fats do not readily become rancid when heated in enameled containers, while they do turn rancid before long when heated in any metallic container. Caramelization of sugars is much slower in enamel than in metallic vessels and this considering the same amount of evaporation or other heating being accomplished when making the comparison. As can readily be seen, this permits obtaining lighter color

in many varieties of manufactured food products. With some of the more acid foods, on the other hand, metals have a considerable bleaching effect, tending to destroy the rich natural colors and producing uninviting caramel-like colors and tastes.

The relative effects of copper and enamel in promoting caramelization in hot cane sugar sirup is indicated in Fig. 4. Curve 1 indicates the discoloration produced by various periods of heating in contact with copper, whereas curve 2 indicates the color change when heated in contact with enamel. The heating conditions were such that the same amount of heat was being transferred per unit area in the two cases.

Still another field where enameled equipment presents its advantages is in the manufacture of pharmaceutical and chemical products. Here the acid-resistant types of enameled ware offer great advantages. In many cases

FIG. 9. WHOLE MILK STORAGE TANKS

the glass lining, in preventing metallic contamination, avoids the necessity of special purification of the products. For some operations metallic equipment can be used if certain strengths of acids are maintained, but rarely do these concentrations permit the largest yields. With acid-resistant glass-lined units, concentrations of acids to permit the largest output can always be employed. Many chemical processes involve strong acid reactions which can be carried out successfully only

FIG. 10. PASTEURIZING VATS

in glass or acid-resistant enamel, and in such cases the ruggedness and strength of enameled units make the latter far superior.

The variety of uses for enameled equipment is practically without limit. It may be worth while, however, to consider a few of the typical uses for enameled ware and why it is well adapted for such uses.

Glass-Lined Beverage Equipment.—Enameled equipment has become a standard material for the manufacture of beverage sirups. The flavors are extracted, compounded and colored in steam-heated kettles. Sugar sirups are prepared by dissolving sugar in water and the resulting sirups are then blended with the various flavoring materials. The finished product is frequently held in large enameled storage tanks which supply the bottling machines. The same units are used interchangeably for making many varieties of sirups.

Enameled Units for Flavoring Extracts.—The manufacture of some types of flavoring extracts involves

FIG. 11. CONDENSED MILK STANDARDIZERS

processes very similar to those used in the preparation of beverage sirups. Orange or lemon extracts and similar products are manufactured by dissolving the flavoring oils in alcohol and storing in airtight enameled tanks. Vanilla extracts are obtained by alcoholic extraction of vanilla beans. Enameled percolators are used in both the hot and cold processes. The finished product is bottled frequently with the aid of enameled filling tanks. When non-alcoholic extracts are made, the extract liquor is concentrated in glass-lined vacuum pans, the vanilla solids being held in solution by glycerine. Recently various non-alcoholic flavoring emulsions have been put on the market. These are usually essential oils emulsified with vegetable gums. Enameled mixing machines are frequently used, because they permit obtaining lighter colored emulsions.

Fruit Juice Equipment.—Glass-lined equipment has been found very adaptable in the manufacture of fruit juices. Fruits such as loganberries, grapes, etc., are preheated in jacketed enameled kettles. After pressing, the juice is held in horizontal storage tanks to permit particles of fruit pulp to settle out. Jacketed enameled kettles are then used for pasteurizing the product before bottling.

Enameled Jam and Jelly Kettles.—The preparation

FIG. 12. MILK TRANSPORTATION TRUCK

FIG. 13. MILK TRANSPORTATION CAR

of fruit juices for making jellies involves a very similar procedure. The juice, after being clarified by settling in a horizontal storage tank, is boiled up with an equal volume of sugar, and, when concentrated to the proper consistency, is run immediately into an enameled jam cooler, where it is cooled to stop any further loss of color before bottling. It has been found that a better flavored and richer colored product is obtained if jellies are concentrated under vacuum in enameled vacuum pans built for that purpose. The vacuum system also eliminates the necessity of having a jam cooler.

Enameled Equipment in the Tomato Industry.—A better color and flavor are the aim of manufacturers of food products. Many types of industrial equipment do not produce as good a finished article as that which the housewife can obtain using small utensils, and naturally she considers the value of the products by the comparison. The tomato industry illustrates very well the advantages which enameled equipment possesses, when the improvement in color and flavor, which it permits,

FIG. 14. ICE CREAM MIXER AND PASTEURIZER

is considered. Enameled tomato pulp cookers are in very common use for concentrating tomato pulp. The finished pulp is stored in large enameled storage tanks, being held until converted into tomato paste or various tomato products such as are used for making purée, catsups, etc. The problem of keeping the enameled units clean is very simple. Records, kept over long periods of time, show that the products manufactured have a much lower bacteria count than those made in other equipment.

Enameled Equipment in the Milk Products Industries.—In the milk and milk products industry sanitation and freedom from metallic flavors must receive greater consideration than in most other food industries. For such work enameled equipment has found great favor. Rectangular vats are used for receiving and weighing

FIG. 15. CREAM AGING TANK

the milk as it comes from the farmer. From these vats the raw milk is pumped over tubular coolers and into closed enameled tanks equipped with brine-cooled jackets. The milk is pasteurized in steam-heated enameled vats and then cooled and bottled. In the condensed milk industry the milk is received and held in similar manner. It is preheated in enameled hot wells and after being concentrated in vacuum pans is run into large enameled standardizing and storing tanks, where the entire day's output is mixed to a uni-

FIG. 16. MINCE MEAT COOKERS

form blend. Enameled motor trucks and tank cars are now replacing cans for collecting milk and bringing it to central receiving stations. Usually ice cream is made by mixing condensed or powdered milk, butter, sugar and other ingredients in steam-jacketed enameled tanks. The mixture is pasteurized in the same apparatus and is immediately homogenized. It is then aged several days in enameled aging tanks to improve its flavor and texture. Enameled units are also available for neutralizing and ripening cream for butter manu-

FIG. 19. PHARMACEUTICAL MIXING AND FILLING TANKS

facture and for preparing starters to produce proper flavors during this ripening. Enameled vats are used in preparing cheese, churning oleomargarines and nut butters with ripened milk, rendering lard for oleomargarines, and in many other like operations.

Applications in Other Food Industries.—The list of processes where enameled equipment is used, not only

FIG. 17. SALAD DRESSING FILLER

because it is applicable but mainly because it has many advantages, is far from being exhausted. In many food industries such as the manufacture of gelatine, invert sugar, mince meat, the blending of honey, making prepared mustard, refining edible oils, mixing salad dressing, cooking tomato catsup and pasteurizing vinegar, enameled equipment is now used. Time is not

FIG. 18. PHARMACEUTICAL STORAGE TANK

available for describing many possible applications. There are still a few uses of different types which merit mention.

Enameled Equipment for Pharmaceutical Purposes.—One would naturally expect manufacturers of pharmaceutical products to equip their factories quite extensively with enameled apparatus, and such is the case. Enameled equipment has been successfully applied in the manufacture of cod liver oil emulsion, camphor ointment and similar emulsions. Alcoholic soap for

tooth pastes is prepared in closed enameled tanks and the various ingredients, such as glycerine, flavoring oils and chalk, are incorporated using the same apparatus. Numerous varieties of sirups, elixirs, antiseptics and medicines are mixed in enameled tanks and held in storage in other closed tanks until ready for use. The mixing of face creams, evaporation of metallic citrates, extraction of alkaloids, preparation of synthetics such as barbitol, veronal, dichloramine T and many other pharmaceutical preparations are carried out advantageously employing enameled equipment.

Chemical Uses for Glass-Lined Equipment.—The difference between pharmaceutical and chemical operations does not permit of a sharp division. On one hand we have the preparation of aspirin, and on the other the evaporation of thorium nitrates. Enameled equipment is applicable to both. In fact, in each case indicated it is practically essential. The field of chemical operations involves such problems as the preparation of pure

FIG. 20. TANKS USED IN PREPARING SYNTHETIC DRUGS

inorganic salts by evaporation, the distillation of compounds such as acetic anhydride or the chlorination of aromatic compounds. In each, enameled evaporating dishes, stills or reaction kettles are very applicable. In fact their use frequently eliminates purification processes which other types of equipment usually make necessary, and there are many other chemical processes eventually connecting with our everyday life which are carried out using glass-lined equipment. Rare earth bromides used for luminous paints are evaporated in enameled dishes. Platinum chloride solutions are similarly processed before refining. Tartaric acid and cream of tartar for use in baking powders are boiled up with charcoal and crystallized in enameled pans. Many dyestuffs and intermediates are prepared using enameled reaction kettles. And so the list goes on, but the above examples are perhaps more than sufficient.

A BROAD FUTURE

Enameled equipment has not been applied to all industrial processes with their varied demands. In some cases its use is rather recent. Often the manufacturer, searching for the best, has tried enameled equipment for his purpose with marked success. A great many possibilities still remain untried. The uses to which enameled equipment has been applied have pointed out that it has certain advantages which may be improvements in any process and have also pointed out an occasional drawback for its application. Being familiar with some of the various types of work wherein it is

FIG. 21. JACKETED EVAPORATING DISHES

successfully used, new uses may suggest themselves and their possibilities be considered by comparison. If the preceding notes have, in such a way, pointed out the nature of the field of enameled equipment, then their purpose has more than been accomplished.

Cement Specifications for Foreign Countries

The specifications that the various countries of the world use in buying portland cement have been summarized in a chart that has just been issued by the Bureau of Standards of the Department of Commerce.

Cement is an international building material and thirty-two countries of the world have specifications for portland cement, twenty of which differ in important details. Twenty-five others use the specifications of other countries in assuring the quality of the cement used in construction within the country, and many others accept the cement if it passes the tests of the country in which it is made.

Though the specifications differ in details and values, they include the same kind of tests in most cases. These are tests for chemical composition, specific gravity, fineness of grinding, setting time, soundness, and tensile and compressive strength.

In this country, there is one universal specification for portland cement, which has been adopted by the commercial interests and testing engineers as well as the Government.

Italian Olive Oil Industry

In 1918 583,600 hectares was cultivated exclusively with the olive tree, and 1,711,100 hectares with this tree and other plants, the total production of olives reaching 17,244,000 quintals, and that of olive oil 2,800,000 hectoliters. The greatest production of olive oil was in the Puglia region; then came Sicily, Calabria, Campania, Tuscany, Abruzzi, Lazio, Umbria, Sardinia, Basilicata, Liguria, Marche, Emilia, Lombardia and the Veneto.

At present the most important region in Italy for the production of the olive oil tree is Puglia, where 300,000 hectares is cultivated exclusively with it, and about 200,000 hectares with it and other plants. In other Italian regions the hectares devoted to olive tree culture are much below such figures. Piedmont is the only region that does not produce olive oil, owing to its colder climate. The exportations of olive oil (edible) increased during the first six months of this year, reaching 1,394 tons, against 798 tons during the same time last year.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Polymerizing Fatty Acids.—Unsaturated fatty acids to be polymerized are converted into alkali salts free from glycerine, and these salts are boiled with caustic lyes, such as caustic soda of 10-12 deg. Bé., to settle out albuminous and other impurities, precipitated out with common salt, heated in an autoclave at 180-214 deg. C. for at least 3 hours, afterward concentrated at constant pressure until the soap contains at least 75 per cent of fatty acids, and then heated in the closed autoclave at 180-214 deg. C. until the desired degree of polymerization is obtained. The purification of the alkali salts admits of lower temperatures being employed so that fish oils, refuse oils, and other impure oils can be treated satisfactorily. (Br. Pat. 166,236. De Nordiske Fabriker De-No-Fa Aktieselskap, Christiania. Sept. 7, 1921.)

Amino Compounds.—Amino compounds are prepared by passing nitro compounds such as nitrobenzene and nitrotoluene, in the vapor phase and together with hydrogen, water gas, etc., over or in contact with a copper-containing catalyst. In place of hydrogen as such there may be employed a body such as secondary butyl alcohol, which is capable of being dehydrogenated under the conditions suitable for the reduction of the nitro compounds, in which case there is obtained in addition to the amino compound, methyl ethyl ketone, or, if methyl alcohol is employed, the reaction product of formaldehyde and aniline. The copper-containing catalyst in a dense porous condition is produced by fusing cupric oxide, cooling it and breaking it into pieces; if desired, the mass may be wholly or partly reduced in a current of hydrogen after the cooling stage. Instead of cupric oxide, a copper salt, such as the nitrate or carbonate, capable of producing cupric oxide on heating, may be used as starting material. The catalyst can be revived by heating in air to temperatures between 300 and 1,000 deg. C. (Br. Pat. 166,283. D. A. Legg and M. A. Adam, both of London. Sept. 7, 1921.)

Dyes Derived From Anthracene.—Vat dyes are obtained by heating 2-aminoanthraquinone with caustic potash in the presence of a non-hydroxylic diluent or solvent—for example aniline, naphthalene, liquid paraffine or toluene; temperatures of 180-250 deg. C. are suitable. According to examples: An impure 1:2:2':1'-N-dihydroanthraquinoneazine dyeing green shades is obtained by boiling 2-aminoanthraquinone with aniline and caustic potash; a pure 1:2:2':1'-N-dihydroanthraquinoneazine dyeing blue shades is obtained by boiling 2-aminoanthraquinone with naphthalene, caustic potash, and potassium nitrate. (Br. Pat. 166,297. F. W. Attack, Manchester, and J. Anderson, St. Andrews, Fifeshire. Sept. 7, 1921.)

Cellulose Ethers.—Cellulose derivatives, suitable for the same or similar applications to the known cellulose ethers and esters, are prepared by reacting on cellulose or its conversion products with halogen esters of glycols or of polyhydric alcohols, or of their ethers—for example, ethylene or propylene chloride or chlorhydrin, glyceryl chlorhydrins, epichlorhydrin and monochlorether; if the ester contains free hydroxyl groups, then such groups are retained in the resulting cellulose derivative. The reaction is carried out in the presence of basic substances, preferably caustic alkalis, and it is preferred to start with cellulose or a conversion product not soluble in alkali and as little depolymerized as possible; it is preferred to employ in the reaction limited quantities of water, say from no water up to four times the weight of the cellulose taken, but preferably between one-half to one and a half times such weight, and preferably a total amount of alkali as would correspond to a 50-75 per cent or even 95 per cent

solution in the water present or added; usually the reaction is carried out at about ordinary temperature, and preferably with cooling to about 0 deg. C. or lower; and the reaction may be carried out with the addition of diluents or solvents such as benzene and in the presence of contact substances such as copper powder, or copper salts or hydroxides. In examples, cellulose is impregnated with 50 per cent caustic soda solution, kneaded with ethylene chlorhydrin or glyceryl monochlorhydrin while cooling to 0 deg. C., with subsequent additions of powdered caustic soda and chlorhydrin; alternatively, the cellulose may be impregnated with water and the caustic soda added in powdered form. The whole of the caustic alkali may be added prior to the treatment with halogen ester, and the ester may be incorporated all at once or in portions or continuously during the process. Mixed cellulose derivatives may be obtained by the introduction of different groups or residues of the class referred to, or by the introduction of other ether groups such as alkyl, benzyl and homologous groups. (Br. Pat. 166,767. H. Dreyfuss, London. Sept. 14, 1921.)

Distilling Ammoniacal Liquor.—Heated ammoniacal liquor is sprayed in succession into two or more evaporating chambers 1, 2, the pressure in the first chamber being utilized to effect the spraying into the second. The liquor may be passed through an intermediate chamber *s* in which it is mixed with a reagent to liberate fixed ammonia. The chambers 1, 2 are heated by flue gases circulating in jackets *f*. The ammoniacal liquor is preheated by passage through tubes *k* in the jackets. Connecting-pipes *u*, *u'* serve to pass the gases generated during the heating of the liquor in the tubes *k* to the collecting main *r*, which leads to a saturator

for the formation of ammonium sulphate. If pure ammonia is to be separated, the first evaporating chamber is surmounted by a column up which the vapors pass and down which a portion of cold ammoniacal liquor flows and removes ammonia from the vapors. The liquor falls through the perforated top of the spraying chamber. The liquor from the base of the chamber is passed through a vessel *s* and then in succession through spraying chambers from which ammonia gas is withdrawn. (Br. Pat. 167,719. Holmes & Co., Ltd., W. C. and M. Boocock, and W. Wyld. Leeds. Oct. 5, 1921.)

Lubricants.—Lubricating oils are obtained by blowing air or oxygen through a mixture of hydrocarbon oil and a catalyst consisting of a manganese, lead or mercury compound, maintained below the cracking point of the oil and between 50 and 300 deg. C. until 0.2 to 1.0 per cent fatty acid is produced. Volatile products may be permitted to escape, or any desired portion may be retained as by flowing the oil and air or oxygen in the same direction and cooling sufficiently to condense the desired portion. The product may be blended with other hydrocarbon lubricating oils, vegetable or animal oils or fats, alkali, soap or graphite. (Br. Pat. 167,789. J. Harger, Liverpool. Oct. 5, 1921.)

Current Events

in the Chemical and Metallurgical Industries

More Plants Increasing Operations

Glass. The Libbey Glass Co. has arranged production on a full 24-hour working basis at its Sandusky, Ohio, plant.

Paper. The Young & Goodfeller Paper Co., Bently Springs, Md., has resumed operations at its local Eagle Mill, following a suspension of manufacture for several months. New machinery has been installed in certain departments of the plant during the idle period.

The Whalen Pulp & Paper Co., Toronto, Ont., is perfecting plans for the early resumption of production at its paper mill in the Swanson Bay section, near Prince Rupert, B.C. Other plants of the company at Port Alice and Howe Sound are now in operation.

The Hinde & Dauch Paper Co., Sandusky, Ohio, has placed its local mills on a normal operating basis. The No. 1, main plant, is running on full time, 5½ days a week; the No. 2, or West End mill, is operating on a 6-day week schedule.

Chemical. The Davison Chemical Co., Baltimore, Md., is now operating its local plant on a basis of about 80 per cent of normal. It is stated that there is a marked increase in demand for sulphuric acid, one of the principal products of the factory.

Leather. Practically all of the tanneries at Wilmington, Del., are taking on additional employees for increased production. It is said that the larger local plants will reach a pre-war basis of manufacture at an early date.

Metals. The New Jersey Zinc Co., Palmerton, Pa., is increasing manufacture at its local plant in the line of oxides and lithopone, and additions are being made to the working force.

The Rosario Mining Co., Tegucigalpa, Honduras, has resumed operations at its local silver mines, following a curtailment of a number of months.

Tin Plate. The American Sheet & Tin Plate Co. began operations at twenty additional mills at its New Castle, Pa., plant Nov. 20, bringing production up to a point of about 90 per cent of normal; a 5-day week schedule will be operative. Operations have also been resumed on full time, working three shifts, at the Monesson, Pa., mills of the company, effecting 100 per cent or normal production at this plant. It is announced that the Shenango, Pa., works will also be resumed under full capacity, where twenty out of thirty mills have been running.

Coke. The H. C. Frick Coke Co., Uniontown, Pa., has placed 850 additional ovens in blast at its works, bringing operations up to a total of about 2,000 ovens and giving employment to approximately the same number of men. The majority of the ovens have been idle since last March and April.

The W. J. Rainey Co., Inc., is operating 150 ovens at its Mount Braddock, Pa., plant, and 100 ovens at the Elm Grove, Pa., works.

Iron and Steel. The Interstate Iron & Steel Co., Chicago, Ill., has increased production to about 50 per cent of normal at its local plant.

The American Steel Foundries Co., East St. Louis, Ill., has resumed production at its local plant, following a shutdown since last February. Employment will be given to about 800 men. The company also reopened its plant at Alliance, Ohio, Nov. 14, with a working force of about 300 men, which will be increased gradually from week to week.

The Thomas Iron Co., Alburtis, Pa., is planning to blow in its Lockridge furnace early in December.

The National Tube Co., McKeesport, Pa., has placed another furnace in blast at its local works, making three out of four furnaces now in service.

The National Malleable Castings Co., Sharon, Pa., has increased operations from 5 to 6 days a week.

Dye Investigation Not Ordered

An unsuccessful effort was made by Senator King, of Utah, during the closing hours of the extra session of Congress to obtain action on the resolution proposing to investigate the dye industry and its efforts to influence legislation. Senator King objected to the action of the Judiciary Committee in limiting the investigation to the alleged dye lobby and to the alleged existence of a dye monopoly. He said that any investigation should include a probe of the efforts made to influence the federal dye control agency and various other activities of dye interests.

Had Senator King been willing to accept an amendment by Senator Frelinghuysen, of New Jersey, that the investigation be broadened so as to allow the committee to search into the activities of importers of dyes, the probe doubtless would have been ordered. Instead, he tried to override the Frelinghuysen suggestion by demanding a vote on the measure as reported by the Judiciary Committee. The absence of a quorum was developed and a motion that the Senate adjourn *sine die* put an end to the effort.

Senator Frelinghuysen expressed the opinion that the Senate should know whether or not the importers are controlling or influencing the dye market or the trade in dyes. He said that neither the dye nor the chemical industry fears any investigation, but that something might be revealed if the practices of importers were laid bare.

Senator McCumber, of North Dakota, expressed the opinion that an investigation of the character proposed by Senator King would be of doubtful value. He said that matter already has been the subject of extended inquiry and that enough testimony has been taken to enable anyone concerned to determine "whether or not there has been such a propaganda as is supposed to influence Senators, and whether or not the dye industry is a monopoly."

Senator Moses, of New Hampshire, declared that there is a vast amount of evidence on the subject that never has been presented to a congressional committee. He declared that he personally has evidence concerning the activities of dye interests in New Hampshire which never has been revealed. Senator King added that there should be an investigation "that will investigate—that will get all the facts relating to this monopoly, its activities, its sinister purposes, its reprehensible if not corrupt methods of operation, its persistent efforts to control Congress and to secure legislation that will enable it to destroy all competition and put millions in the pockets of a favored few."

Senator Brandegee, of Connecticut, not only expressed the opinion that the investigation would amount to nothing but stated that it is not the business of Congress to determine what is and what is not a monopoly. He held that it is a judicial question for the courts to decide. "It would amount to nothing," he said, "to resolve that in our opinion the dye industry is a monopoly."

Additional Papers for the Baltimore Meeting, A.I.C.E.

The final program for the meeting of the American Institute of Chemical Engineers, which will be held in Baltimore, Dec. 6 to 9, contains four papers which were not included in the program printed in our issue of Nov. 16. L. W. Wallace, executive secretary, F.A.E.S., will address the institute at 10 a.m., Dec. 6. During the morning of Dec. 8, Prof. J. H. James will present a paper on "Some New Products From Petroleum" and Dr. Robert M. Yerkes will discuss the research information service of the National Research Council. The fourth paper, which is scheduled for 10:15 a.m., Dec. 9, is "Regenerative Evaporation," by Prof. W. L. Badger.

Program, American Petroleum Institute Meeting

As announced in a preliminary bulletin, the program of the second annual meeting of the American Petroleum Institute at the Congress Hotel, Chicago, Dec. 6, 7 and 8, will include general sessions in the afternoons and evenings, and technical sessions Tuesday and Wednesday mornings.

Among the addresses at the general sessions will be:

"The Current Year in the Petroleum Industry," Walter C. Teagle, president Standard Oil Co. of New Jersey; "The Mid-Continent Refiner," D. W. Moffitt, vice-president, Cosden & Co.; "Looking Ahead," Harry F. Sinclair, chairman of board, Sinclair Consolidated Oil Corporation; "Some Things We Might Be Doing," Henry L. Doherty, president, Cities Service Co.; "As John Bull Views It," Sir John Cadman, formerly his Majesty's petroleum executive; "World Highways of Trade," A. C. Bedford, chairman of board, Standard Oil Co. of New Jersey.

The technical program is as follows:

TUESDAY, DEC. 6, 10 A. M.

General topic, "The Motor Fuel Problem."

Presiding, R. D. Benson, president, Tide Water Oil Co.

"Quantitative"

"Quantitative Survey of Petroleum Industry From the Standpoint of Production of Motor Fuel," Van H. Manning, director of research, American Petroleum Institute.

"Quantitative Survey of the Automotive Industry, Present and Prospective," Edward S. Jordan, president, Jordan Motor Car Co.

"Qualitative"

"Requirements of Motor Vehicle Fuel," H. M. Crane, engineer.

"Qualitative Limitations in Refining and Marketing," Frank A. Howard, manager, Development Department, Standard Oil Co. (New Jersey).

"Volatility of Motor Fuel as Marketed in the United States," N. A. C. Smith, petroleum chemist, U. S. Bureau of Mines.

"What Constitutes True Volatility," R. E. Wilson, director of research, Laboratory of Applied Chemistry, Massachusetts Institute of Technology.

"Present Variations in the Quality of Motor Fuel—Its Extent and Causes," C. K. Francis, chief chemist, Cosden & Co.

General discussion.

WEDNESDAY, DEC. 7, 10 A. M.

General topic, "The Motor Fuel Problem."

Presiding, Capt. J. F. Lucey, president, Lucey Manufacturing Corporation.

"Limitations Imposed on Economy by Volatility Changes," F. C. Mock, research engineer, Stromberg Motor Devices Co.

"Practical Effects of Too Low Volatility," O. C. Berry, chief engineer, Wheeler-Schebler Carburetor Co.

Thirty minutes of general discussion.

General topic, "Value of Research to the Petroleum Industry in General."

Discussion by:

David Beecroft, president, Society of Automotive Engineers; T. G. Delbridge, chief chemist, Atlantic Refining Co.; A. W. Ambrose, petroleum technologist, U. S. Bureau of Mines; K. G. Mackenzie, chief chemist, the Texas Co.; W. C. Platt, president, *National Petroleum News*; J. R. Stockton, vice-president, Producers & Refiners Corporation.

Executive Committee, Division of Chemistry and Chemical Technology, N.R.C., to Meet

The executive committee of the Division of Chemistry and Chemical Technology of the National Research Council will meet in Washington on Monday, Dec. 12, to consider the progress of investigations and the committee work which will be supported for the coming year. Any persons interested desiring to make suggestions regarding plans for the work of the division should send them before that date to Dr. F. G. Cottrell, chairman, 1701 Massachusetts Ave., Washington, D. C. Other members of the committee are: Julius Stieglitz, vice-chairman; Colin G. Fink, W. F. Hillebrand, R. B. Moore and W. D. Bancroft.

Federated American Engineering Societies to Review Progress at Annual Meeting

In a statement summarizing general conditions in the Federated American Engineering Societies, the executive secretary, L. W. Wallace, expresses the belief that the federation has made substantial progress. At the annual meeting of the American Engineering Council to be held in Washington Jan. 5 and 6, this progress will be shown by reports covering activities in many fields.

"Unquestionably," says Mr. Wallace, "the federation has made favorable and permanent contacts in Washington. Through the activities of Congress and of the new federal administration, we have had the opportunity of rendering some really constructive service. We feel, however, that the great body of engineers are not adequately informed of the organization of the federation, of its aims and purposes and of its activities.

"This lack of information is serious and until engineers in general are more fully informed, we shall not hope to function to the best advantage. The executive board should therefore give serious consideration to methods of informing engineers as to the aims, policies and activities of the federation. Some member societies have been and are now perhaps rather indifferent to a continuation of their affiliation. As far as we have been able to ascertain, this condition is due to the officials and the members of such organizations not being fully informed.

"While it may be true that during the first year the federation has not been able to accomplish all that was expected on the part of some and that it has not fully found itself, so to speak, yet the progress has been such as to justify optimism rather than pessimism as to the future usefulness of the federation. The federation has been fairly well established in the minds of the public and in Government circles. This is evidenced by the character and quantity of publicity that the federation has received.

"The report of the publicity committee to the executive board clearly shows that the activities of the federation have attracted attention and notice in all of the leading cities and many of the towns and villages of this country. Constant reference is being made to the federation in the technical, daily and periodical press of every description. It is also being referred to in the official proceedings and publications of many commercial and trade associations. This alone is one reason for encouragement."

Sectional Meetings of Steel Treathers

The American Society for Steel Treating is planning to hold sectional meetings at quarterly intervals in addition to its annual meeting and exhibit. By holding the directors' meetings at the same time, a double purpose may be served: The national officers may become acquainted with regional activities with the minimum travel, while many local members who cannot afford to attend the convention—which may be at some distance—will be able to get together for an afternoon and evening social and technical session. The first of these meetings will be held in New York City some time in March, 1921. It is hoped that it will attract the membership of chapters in Baltimore, Boston, Bridgeport, Hartford, Lehigh Valley, New Haven, Schenectady, Syracuse, Providence, Springfield, Washington and Worcester. Walter F. Graham, Truell Court, Plainfield, N. J., is in charge of the arrangements.

Muscle Shoals Deal Likely to Go Through

A definite recommendation by the Secretary of War favorable to Henry Ford's proposal to develop Muscle Shoals probably will be made to Congress shortly after the opening of the regular session. Certain details of the negotiations are not complete and have been delayed by the illness of Secretary Weeks. It is believed, however, that an agreement will be reached without difficulty, although alternative plans may be submitted to Congress.

Muscle Shoals was discussed at a meeting of the Military Affairs Committee of the House on Nov. 21. It was revealed that the committee is thoroughly in sympathy with the policy of having this water power developed by private interests.

Minerals Separation Claims 12 Millions

At the hearing before the Master in the accounting proceedings resulting from the infringement suit against the Butte & Superior Co., which was held in New York, Nov. 3 to 19, Minerals Separation presented a claim of \$11,904,913.95 as representing the profits, gains and advantages which the Butte & Superior Co. had realized from its use of the Minerals Separation patented processes.

The magnitude of this amount is due to the setting up of water gravity concentration as the standard of comparison. This standard, it was testified by Minerals Separation, was the only one which was available to the Butte & Superior Co. It was also testified by Minerals Separation witnesses that 65 per cent recovery of the zinc and a 48 per cent grade of concentrate was the best result which it would have been possible to have obtained upon Butte & Superior ores by water gravity concentration. Applying the difference between this result and the results which admittedly had been obtained through the operation of the Minerals Separation patented processes over the period of years from 1913 to 1919, during which period infringement had been adjudged, the above-mentioned claim as to amount of damages was arrived at.

It would therefore seem that the amount of resulting damages resolves itself largely into a question as to the standard of comparison which may be found to be applicable. Judge Bourquin, in the United States District Court of Montana, has rendered an opinion as to the law governing the available standard of comparison (see *CHEM. & MET. ENG.*, Sept. 7, 1921, page 484), and since this opinion is based upon a motion by Minerals Separation in this very case, the application of this opinion may have the effect of very considerably modifying the figure above given, since by this opinion the Butte & Superior would not seem to be restricted to water gravity concentration as a standard, nor if so, is it likely that the percentages given by the plaintiff will remain unchallenged in the defense which will be submitted when the hearings are resumed Feb. 14, 1922.

Meeting of Synthetic Organic Chemical Manufacturers Association

The adjourned organization meeting of the Synthetic Organic Chemical Manufacturers Association was held Nov. 18 in the Pennsylvania Hotel, New York City. A large and representative attendance was present. During the meeting there were added to the membership by election thirteen active members and one associate member.

W. S. Cashman of the Grasselli Chemical Co., Cleveland, Ohio, was elected a member of the board of governors of the association, having been recommended by the Intermediate Section.

The association is preparing the issuance of a pamphlet setting forth the address of Secretary Hoover which preceded the inaugural meeting in the city of Washington on Oct. 28, extracts from the constitution, and a statement covering fully the objects and purposes of the association.

The following resolution was unanimously passed:

Whereas it has been brought to the attention of this association that it has been reported that the dyestuff manufacturers of the United States are opposed in the tariff legislation to what is known as the American valuation plan, therefore be it

RESOLVED, That the president be instructed to advise the National Manufacturers Association of the United States that it is the sense of this meeting of the Synthetic Organic Chemical Manufacturers Association, manufacturers in the United States of synthetic organic chemicals, including dyestuffs, that the statement, reported in the *New York Times* of Nov. 18, as made by Wilbur F. Wakeman, secretary of the American Protective Tariff League, at a meeting of manufacturers held at the Hotel Pennsylvania, Nov. 17, under the auspices of the National Association of Manufacturers of the United States, to the effect that the administrative feature of the tariff bill now under consideration by the Finance Committee of the United States Senate, providing for American valuation in the determination of ad valorem duties, was opposed, among other influences, by "the domestic dye manufacturers' bloc" is

strongly resented, and the association desires that it be clearly understood that it is in entire sympathy with all measures necessary to encourage and adequately protect all American manufacturing industries, including the American valuation plan.

The meeting adjourned to Dec. 9 at 2 p.m., at the Hotel Pennsylvania, New York City.

International Labor Conference to Adopt Convention on Use of White Lead in Painting

Supplementing the item published on page 980 of the November 23 issue, the Washington office of the International Labor Office reports that the International Labor Conference at Geneva adopted, by a vote of 76 to 3, a resolution to draft a convention on the subject of the use of white lead in painting.

The resolution provides for the prohibition of the use of white lead in interior painting, except in factories and railway stations. However, this portion of the convention does not become effective for 6 years. The convention also provides certain regulations for the use of white lead in other forms of painting, such as measures for protection in dry scraping, in spraying with white lead pigments, providing adequate facilities for washing to those using white lead pigments, etc.

The subject has now gone to the drafting committee of the conference, which will draw up the convention in its final form. Owing to the character of the vote above mentioned, there is little doubt that the draft convention in its final form will receive the necessary two-thirds majority.

New Jersey Clay Workers to Hold Annual Meeting

The New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society is perfecting arrangements for its annual meeting to be held at Rutgers College, New Brunswick, N. J., Dec. 16. An interesting technical program is being developed by the committee in charge, which includes Prof. George H. Brown, secretary of the organization; Roy H. Minton and Fred A. Whitaker, both of the General Ceramics Co.; Leslie Brown, of Lenox, Inc.; and A. D. Forst, Jr., of the Robertson Art Tile Co. It is expected to have five or more papers on pertinent subjects, with sessions held both morning and afternoon. The annual election of officers will also take place at this time.

Chemical Warfare at the Arms Conference

The limited discussion of chemical warfare which has been had in connection with the Conference on the Limitation of Armament has revealed that it is very generally conceded that chemical warfare has come to stay. The probabilities are that the conference will not go into the details of the use of gas in warfare and that this weapon will be affected only as there may be agreement to make reductions in all military activities.

Gas-Free Ingots

Metallurgists have for years been searching for means to prevent the absorption of gas by the steel during the melting process and there have been several attempts to devise a method to melt in vacuo. Such a plan, emanating from Norway, is the subject of experiment at the present time at the University of Sheffield, England, along the lines of what is known as the "vacuum converter press." The charge to be converted is melted in a vessel; when the contents are thoroughly fluid the vessel is connected to a vacuum pump, which draws out all the gases that remain, and the vacuum is then sealed and the steel cools without being able to reabsorb. Hence the ingot is wholly sound. According to *The Ironmonger*, the experimenters are satisfied that the idea of a vacuum converter has been definitely proved to be of practical value and that it must be reckoned with in the future of the steel trade. Razor steel of unusually fine quality has been made by the process, and it is claimed that it will be equally successful for making all high-quality grades of cutlery steel at less cost than the present crucible process.

British Discuss Plan to Facilitate Production of Denatured Alcohol

At a London conference recently convened by the Empire Motor Fuels Committee of the Imperial Motor Transport Council of delegates from Empire Governments, at which representatives of British India, the Australian Commonwealth, the Union of South Africa, New South Wales, Tasmania, British Columbia, Quebec and the Crown Colonies were present, a resolution was passed for submission to the appropriate departments of the various governments concerned. The conference discussed the present customs and excise restrictions on alcohol and suitable methods for denaturation of alcohol, and the resolution urges that the various Empire Governments be requested to consider the necessary action to facilitate the production and distribution of industrial and power alcohol throughout the empire. It recommends that each Empire Government should consider the advisability of putting forward for consideration at a further conference proposals regarding the adoption of common methods of, and formulas for, the denaturation of alcohol within the empire so as to cheapen and facilitate operations.

Connecticut Valley Section, A.C.S., Elects Officers

At the November meeting, held at the University Club, Hartford, on Nov. 14, the Connecticut Valley Section of the American Chemical Society elected the following officers:

Chairman, Dr. J. S. Chamberlain of Massachusetts Agricultural College; vice-chairman, Dr. Hill of Wesleyan College; treasurer, G. B. Hogaboon; secretary, Paul Serx, jr., Massachusetts Agricultural College; executive committee, Messrs. Andrews of New Britain, Wolfendale of Springfield and Kriebel of Hartford; councilors, Dr. C. R. Hoover and Dr. J. A. Newlands.

Following the business meeting a dinner was served at the University Club. About forty were present. Later in the evening Dr. Chamberlain, of Amherst, gave a historical sketch of the work that led to the discovery of vitamins and a brief account of some of the more recent developments.

Citation by Federal Trade Commission

The Federal Trade Commission has issued a formal complaint against the Procter & Gamble Co., of Cincinnati, Ohio. Thirty days is given for answer, after which the case will be tried on its merits.

The respondent, the complaint alleges, manufactures a soap designated as "P. & G., the White Naphtha Soap," and a washing powder designated as "Star Naphtha Washing Powder," neither of which, it is charged, contains naphtha as a constituent ingredient, but contains instead a petroleum distillate other than naphtha to the extent of 2 per cent or less of the whole ingredients of the washing powder. It is further charged that the distillate used is substantially all lost by volatilization or evaporation by the time the commodity reaches the ultimate consumer. Such practice is alleged to be false and misleading and unfair to competitors of the respondent.

Effect of Impurities in Retarding Crystallization

Professor J. H. Walton, of the department of chemistry of the University of Wisconsin, lectured before the Milwaukee Section of the American Chemical Society on November 18 on the subject, "The Influence of Impurities on the Rate of Growth of Certain Crystals." Prof. Walton's talk had particularly to do with the effect of the presence of impurities upon the rate of crystallization, a subject which is both of theoretical and technical interest. His researches show that substances which are hydrated to the greatest extent show the greatest retarding effect. The retardation is best explained by the slowing down of the reaction by which large molecular aggregates are formed during the process of crystallization. Experiments with undercooled formamide solutions show that here also those substances which are solvated to the greatest extent are the ones that show greatest retardation of the velocity of crystallization.

"Tinkering With Scientific Bureaus"

Through the publication in the *Congressional Record* on Oct. 26 of a plan by Arthur McDonald of Washington, to consolidate all Government scientific bureaus in the Smithsonian Institution, wide circulation has been given to a scheme which is not taken seriously in Washington and which does not have the indorsement of the Smithsonian Institution. Dr. Charles D. Walcott, secretary of the Smithsonian Institution, states that the plan was drawn up and circulated without his knowledge or approval. Representative Melvin O. McLaughlin, who inserted the proposal in the *Congressional Record*, states that he is opposed to the scheme himself, but sees no reason why publicity should not be given to the suggestion so that those concerned could accept it for what it may be worth.

It may be recalled that in an editorial in its issue of Oct. 19, CHEMICAL & METALLURGICAL ENGINEERING pointed out the utter fallacy of the proposal and warned its readers against giving the scheme any serious consideration. As a result, however, of the publication in the *Congressional Record*, the various scientific bureaus and the Smithsonian Institution have received a flood of comment aroused by the suggestion.

To Revise Summary of Tariff Information

The Tariff Commission has been requested by the Senate Finance Committee to prepare for the use of that committee a volume similar in character and contents to the Summary of Tariff Information which was submitted to the Ways and Means Committee in January, 1920. The new volume is to contain much of the information which is in the present Summary and, in addition, later notes and statistics regarding changes which have occurred in the industries since the original volume was published.

It will be recalled that some time ago the proposal was made by Dr. Bernhard C. Hesse that trade associations and scientific societies interest themselves in correcting and bringing up to date this valuable source of industrial information. This opportunity is now offered and it is suggested that any of our readers who are interested in the products of Schedule 1—chemicals, oils and paints of the bill H.R. 7456, submit their comments and criticisms to the United States Tariff Commission not later than December 15.

New Oil Companies in October

During the month of October a total of 55 new companies was organized in the petroleum industry with capital of \$50,000 or over, the aggregate indicated investment being \$83,450,000. This is an increase of about \$30,000,000 in combined capitalization over the figures for September, but a decided decrease from the total of \$496,968,000, as was evidenced for similar new companies in the corresponding month of last year.

For the first 10 months of the present year the indicated investment of new companies in this line of industry aggregates \$1,129,913,600, divided among 807 companies. In the same period of 1920 a total of 2,327 new companies were formed, with a combined capitalization of \$2,410,944,700. Since the beginning of the present year, 27 companies have been organized with a capital of \$10,000,000 or greater.

Obituary

WILLIAM H. STENGEL, treasurer of the George Stengel Co., Inc., Newark, N. J., leather manufacturer and son of the late George Stengel, founder of the company, died at his home, 64 Johnson Ave., Newark, Oct. 28, from a complication of diseases. He was fifty-three years of age.

HOWARD THOMAS, vice-president and general manager of the Eastern Oil Co., Buffalo, N. Y., died on Nov. 12, aged fifty-eight years.

Personal

Dr. E. D. BALL, recently appointed director of scientific work for the Department of Agriculture, has been designated as the representative of that department on the research information service committee of the National Research Council. He fills the place made vacant by the resignation of Dr. Carl L. Alsberg. Dr. Alsberg's place on the Division of Federal Relations of the National Research Council has been filled by Dr. Frederick D. Power, for many years the director of the Wellcome Research Laboratory in London, and now in charge of the phytochemical laboratory of the Bureau of Chemistry.

Prof. EDWARD BARTOW, head of the department of chemistry at the State University of Iowa, has just returned from a trip to Tulsa, Okla., where he was engaged in an investigation of the water supply of that city.

ROBERT F. BROWN, formerly connected with the banking firm of Weil, Farrell & Co., Boston, Mass., has been elected treasurer of the Dayton Rubber Manufacturing Co., Dayton, Ohio, with offices in that city.

A. S. CARLTON has been elected president of the Union Chemical Co., Boston, Mass. For some time past he has been vice-president of the company.

BURGESS DARROW has been appointed development manager for the Goodyear Tire & Rubber Co., Akron, Ohio. He is a graduate of the Massachusetts Institute of Technology and has been connected with the company for the past ten years in tire development and compounding work.

W. MCA. JOHNSON has recovered control of his electrothermic zinc-lead process and expects to take steps to introduce it commercially.

Dr. J. A. LECLERC, who is a recognized expert on cereal products and has been associated with one of the large corn mills for a number of years, has been sent as a special trade commissioner to confer with European authorities upon the use of corn grits as a food.

T. A. PATTERSON has severed his connection with the Niagara Alkali Co., Niagara Falls, N. Y., to become technical director of the Belle Alkali Co., Belle, W. Va.

N. A. V. PAULSSON, who as consulting engineer for Corning & Co., Albany, N. Y., has designed an electric iron and steel plant for the Cia Electro Metallurgica Brasileira, has sailed for Brazil to supervise the installation of the furnaces and the early operation of the plant. His address will be Ribeirão Preto, São Paulo, Brazil, for several months.

Prof. J. H. WALTON, of the department of chemistry of the University of Wisconsin, lectured before the Milwaukee Section of the American Chemical Society on Nov. 18, on the subject "The Influence of Impurities on the Rate of Growth of Certain Crystals."

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Nov. 28, 1921.

The chemical market during the past week has shown encouraging signs of increased buying power, although again interrupted by a holiday period. Business in most items has been of a satisfactory nature and producers are optimistic about future conditions. An outstanding feature of the market was the position of caustic soda in foreign fields. Large tonnage sales have been authoritatively recorded among leading manufacturers, with the bulk of shipments going to European and South American countries. It is a source of gratification to know that American producers are again successfully able to compete with European factors. The call for caustic and ash at home has also been renewed. There was some future business placed and

more interest is manifested in covering requirements over next year. Producers have announced a standard price for 1922, although there have been various rumors around the market of different contract prices. Yellow prussiate of soda commanded increased interest from the consuming trade and the market was a trifle firmer at the close of the week. Producers of oxalic acid have been much stronger in their views, and goods at the works were quoted considerably higher. Bichromate of soda is moving in slower fashion with actual sales being recorded at lower figures. Caustic potash has been somewhat overlooked during the week and spot prices were a shade weaker. Imported chlorate of potash was about the most unstable item on the market and holders of good-sized quantities were eager to sell regardless of standard quotations. Consumers of bleaching powder have shown an eagerness for full contract deliveries, and supplies appear to be relatively light on both the imported and domestic material. It can be stated, in general, that the outlook for the chemical market is noticeably improving. There is no doubt that the big shot for expansion depends upon the result of the armament conference. Should all the nations concerned agree to reductions of armament, there will be a prompt response in the foreign exchange market which will mean a big boom in our export trade. Domestic soap, paper, textile and tanning industries are showing more interest in the market and new orders are coming in for larger quantities than noted two or three months ago. Those close to the pulse of trading are of the opinion that the spring months will see trade conditions in a very healthy and normal condition.

CHEMICALS

Prices on *oxalic acid* have moved upward during the past week and at the close producers held prices firm at 14½c. per lb., f.o.b. works. Sales on spot were transacted during the week at prices ranging from 14½@16c. per lb., according to brand and quantity. Leading sellers were not inclined to part with stocks under 15c. at the close of the week. The market seems to have become steady again and higher prices are expected. Spot prices on *prussiate of soda* were a fraction firmer at the close and sales were made at 14½c. per lb., ex-store. Some dealers quoted up to 14¾c. Shipment prices remained unchanged at 14¼c. per lb. c.i.f. New York. Dealers of *bichromate of soda* were not desirous of quoting under 8c. per lb. for spot material, although some business was done down to 7½c. The general quotation ranged from 8@8½c. per lb. for prime goods. The demand has remained moderate with small orders attracting the most attention. Commercial *white arsenic* is quoted by leading producers at 6½@7c. per lb. for spot and shipment material. The demand has shown a slight improvement of late. Second hands still quote the market at 6@6½c. per lb. according to quantity. Recent importations of *chlorate of potash* have placed the market in a very unsettled condition and dealers have had to resort to price slashing in an effort to distribute supplies. The price ranges from 5½@6c. per lb. on imported material for spot. Domestic goods is unchanged at 12c. per lb. f.o.b. works. Sales of *caustic potash*, 88-92 per cent, during the week were reported at 5¼@5½c. per lb. The demand has not shown any signs of improvement and prices are barely steady. Large consumers seem to have well supplied themselves with shipment material. The big encouraging feature of the chemical market was the position of *caustic soda* both here and abroad. There has been a marked improvement in the export field since the beginning of the month with reports varying as to the actual amount of business that was placed. Italy was reported to have bought large tonnages at prices ranging from \$4.80@\$5 per 100 lb. c.i.f. Italian ports. South America is also an added buyer of caustic soda with Argentina doing the most purchasing. Producers stated that the demand for domestic material has shown a steady increase. Several carlots have been moved at \$3.90 per 100 lb., with lesser quantities selling around \$4.10. Manufacturers of *copper sulphate* have not advanced the price of this chemical, although the trade is looking for an upward revision on account of the strength in copper metal. The demand has not been at all encouraging of late and this, no doubt, has kept producers from

advancing prices. The carlot price is 5½c. per lb. for standard 99 per cent, large crystals. The market on soda ash in single bags has not shown much change from the previous quotation. The domestic demand has not been up to the standard and prices remained around \$2 per 100 lb. for carload quantities. Smaller lots commanded up to \$2.40 per 100 lb. Barrels were quoted at \$2.40@2.50 per 100 lb. The trade was somewhat surprised that ash was not included in the recent demand for export.

COAL-TAR PRODUCTS

The coal-tar products market during the past week has shown practically no improvement, with prices in most directions unchanged. Small-lot business seems to be attracting the most attention, with an increased amount of inquiries and orders recorded. Contract business is almost unheard of in the trade, as most consumers feel that the general tendency is toward lower rather than higher levels. Producers and buyers are operating in an extremely cautious manner, but are quite optimistic that business will materially improve with the turn of the year. Stocks in consumers' hands are noticeably light and any upturn in the market will, no doubt, tend to bring a considerable amount of orders. The demand for *benzene* still far exceeds the supply, but refiners are experiencing an improvement in stocks with the increased activity in the steel industry. First hands are quoting 27@33c. per gal. Resale material is extremely difficult to locate. The tone of the *cresol* market is somewhat easier, with prices about 1c. per lb. lower. Quotations range from 15@16c. per lb. The market on *phenol* is stronger and holders of prime material are somewhat firmer in their views. Sales under 10c. per lb. are quite rare and quotations range from 10@14c. per lb. according to quantity and seller. Sales on *metaphenylenediamine* were made down to \$1.05 per lb., but the general quotation was \$1.10@1.15 per lb. The demand continues fair in view of the adverse conditions in the garment trade. Resale quotations on *naphthalene flakes* are around 6½@7c. per lb. The market is a trifle firmer and there is some hope for higher prices. Makers ask 7½c. per lb. for the flake and 8@8½c. for the balls. Sales of *alpha-naphthylamine* were made at 30c. per lb., despite rumors of lower figures. This seemed to be the inside price, with holders asking up to 32c. for smaller quantities. Sales of *aniline oil* were made at 18c. per lb., with some sellers asking up to 20c. The market is reported a shade stronger, with most of the low-priced material either sold or withdrawn from the open market. Makers of *beta naphthol* ask 32c. per lb., with sales made by second hands down to 30c. The tone of the market seems to have noticeably improved, although there are still holders of large sized quantities. First hands on *dichlorobenzene* are holding prices at 6@8c. per lb. The demand is not exceptionally strong, but the general tone of the market is steady.

The St. Louis Market

ST. LOUIS, Nov. 25, 1921.

Since the last letter there has been practically no change in the drug and chemical markets as far as activities are concerned. However, a few minor price changes have taken place, principally upward. The second-hands are generally being eliminated but importers are still very active.

ALKALIS

The market continues firm on *caustic*, with the solid selling at \$4 per 100 lb., point of production in carlots, the flake in drums at \$4.25 per 100 lb. for the 76 per cent solid material. *Soda ash* is in light demand, with free movements, the price remaining at \$3 per 100 lb. in barrels ex-warehouse. The market on *bicarbonate* and *sal soda* remains very quiet, with few sales at \$2.90 and \$2.15 per 100 lb. in barrels respectively.

CHEMICALS, DRUGS AND PHARMACEUTICALS

The market on *acetphenetidin* has been strengthened by the elimination of the price-cutting competition. *Ammonia water* is moving through regular channels. *Ammonium sulphate, pure granular*, continues in good inquiry and demand. *Bismuth salts* are moving in a very lively manner,

especially the *subcarbonate*. Large sales of *bromides* have been reported. Orders for *carbon bisulphide* are dropping off. *Creosotes* and *guaiacols* are commanding a better position and should continue to do so, as these are seasonable products. *Ether* continues to move freely. *Glycerin* has advanced slightly and is now selling at 14½c. per lb. in drums. The demand is very strong and even higher prices may be expected. *Glycerophosphates* are moving in larger volume. There appears to be a better demand for *hypophosphites*. *Hypo* and other photographic chemicals are not so active. *Iodides* are very lively. Of the narcotics, *codeine* is the most active of the group. *Salicylates* are moving in good volume. The *sulphur* market is very sluggish. Prices have not declined, but are not firm by any means, being \$1.35 per 100 lb., carlots f.o.b. mines, for 88 per cent commercial. *Zinc oxide* is in fair demand and movement nominal. Future business looks promising. Price remains at 7½c. in barrels and 7¼c. in bags, f.o.b. works, for the standard brands.

ACIDS

Movement of the heavy mineral acids has been retarded this month owing to customers having anticipated their November requirements at the time of the threatened railroad strike. Factors reduced their price on *acid phosphoric sirupy*. *Acid tartaric* is very steady.

VEGETABLE OILS AND NAVAL STORES

Turpentine is somewhat weaker today than at the last report, having declined from 85c. to 83c. for single barrel orders, with a 4c. differential in 5-bbl. lots. The *castor oil* demand has fallen off slightly, but the price remains steady at 12½c. in barrels and 12c. in returnable drums. *Linseed oil* is slow and steady at the same price prevailing in the last report—namely, 70c., basis raw oil ex-warehouse.

The Iron and Steel Market

PITTSBURGH, Nov. 25, 1921.

Except in tubular goods and tin plate, the finished steel market continues to present an appearance of decided dullness, in contrast with the increasing activity observed up to about the middle of October. That is the appearance seen in market circles, but there is the inconsistent thing that production of steel does not seem to decrease at all. There are some cases of increases and in the aggregate there cannot have been much decrease. Steel ingot production may fairly be estimated at between 40 and 45 per cent of capacity, against the 44 per cent rate shown for October, the highest rate since February.

It is quite certain that mills are accumulating no stocks and it is equally certain that neither distributors nor manufacturing consumers are accumulating stocks. There is a fresh effort to liquidate stocks completely, from the double influence of the inventory date being approached and a general reduction in freight rates being expected.

There seems to be no flaw in the argument that the actual ultimate consumption of steel is maintained and is at what may be considered a fair rate by comparison with earlier months in the year. Yet one of the dull seasons of the year has arrived or is being approached. It seems quite reasonable to assume therefore that consumption is to continue at substantially the recent rate, subject to increases when conditions favorable to an increase develop. Four factors at least should make for eventual improvement, within the discernible future:

1. The approach of spring, which normally brings seasonal increase in consumption, this influence being likely to be felt in February.

2. Increasing easiness in money.

3. General reduction in freight rates, which all have been waiting for, in all probability to come between Jan. 1 and April 1.

4. Further liquidation in building costs, and in readjustment and harmonizing in prices and wage rates generally.

These points relate to the consumption of steel. As to demand upon the steel mills, another point can probably be counted upon. There has been drastic liquidation in stocks of steel in the hands of buyers. Steel prices, already low by comparison with commodities and values generally, continue to sag and are likely to reach a level from which

a slight upward reaction could reasonably be expected. With such a point reached and with stocks in buyers' hands at an altogether unnaturally low level, a stocking up process is extremely likely to be seen, and even if pursued very conservatively this would bring an added demand upon the steel mills. Then there would be present consumption plus an increase in consumption plus a partial restoration of stocks. Within the early months of the new year this may not unreasonably be expected to produce a mill operation of 75 per cent or more.

LINES OF DEMAND

Demand upon the pipe mills seems to have increased somewhat even up to date. It certainly has not noticeably decreased. In the past fortnight the National Tube Co. (Steel Corporation) has increased its active blast furnaces from four to six, partly because of exhaustion of stocks of pig iron, partly because of increased demand. There is an equally fair call for standard pipe and for oil country goods. The latter line does not show the usual seasonal decline in activity, partly on account of sharp increases in oil prices in recent months, partly because there is now more oil territory where winter interferes less. Prices on these lines are fairly well maintained. In line pipe there has been severe cutting, said to be well below the cost of production. Each of the three oil companies in the new Mexia field in Texas contemplates laying a 200-mile mine of 8-in. pipe.

Tin plate mill operations are increasing, being supported by current demand of seasonal character and by the entering of specifications against requirements for the first quarter of the new year, furnishing mills extra employment now, shipments to begin after Jan. 1. The \$4.75 price announced Nov. 3 appears to be well held.

Railroads continue to exhibit interest in rolling stock, first exhibited in practical way in the past two or three weeks.

Bars, shapes and plates appear to be in quite moderate demand in general. Sheets are distinctly duller than a month ago. Wire products appear to have been tapering off, some distributors evidently having accumulated stocks through specifying against contracts made in anticipation of the price advance of Sept. 12.

STEEL PRICES

Bars, shapes and plates are more frequently done at 1.50c. than a fortnight ago, but small orders, down to carloads, usually involve a slightly higher price. The continued sagging suggests that eventually there will be a turning point, which is likely to be at 1.50c. or a trifle less. Sheet prices are in a state of flux. After the failure of the recent attempt of some independents to advance the market from 3c. to 3.25c. prices began to sag, some recent quotations being at 2.75c. or possibly a trifle less. It being intimated that the Steel Corporation was about to announce prices for first quarter, independents have been disposed in the past week to withdraw prices under 3c. for black and 4c. for galvanized, and if this withdrawal proves complete the prices mentioned may be announced for the first quarter. The recent attempt to advance wire from 2.60c. to 2.70c. and nails from \$2.90 to \$3 appears to have been abandoned, not enough contract business being booked at existing prices to justify an advance, while it may be that present prices are being shaded, by extension of old contracts and by other methods.

Pig iron continues dull, with a softening tendency when competitive business is offered. The valley market remains quotable at \$20 for bessemer, \$19 for basic and \$20.50 for foundry, but these prices could possibly be shaded on a round tonnage.

Connellsville coke has continued to weaken, with a slight accumulation on track and with continued failure of additional consumption to develop. Prompt furnace coke is down to a range of \$3@3.10, while foundry is not particularly strong at \$4@4.50. The Trumbull-Cliffs Furnace Co. contemplates blowing in its furnace Jan. 1 and is out with an inquiry for 18,000 tons a month for first quarter or first half, apparently expecting to buy at \$3.25, a price not yet quoted for the period.

Sulphuric, fuming, 20 per cent(oleum) drums.....ton	23 00	23 50	24 00	24 50
Sulphuric, fuming, 20 per cent(oleum) carboys.....ton	31 00	32 00	33 00	34 00
Tannic, U. S. P.....lb.	—	—	.75	.85
Tannic (tech.).....lb.	.45	.48	.50	.55
Tartaric, imported crystals.....lb.	—	—	.26½	.27½
Tartaric acid, imported, powdered.....lb.	—	—	.27½	.28½
Tartaric acid, domestic.....lb.	—	—	—	.35
Tungstic, per lb. of WO.....lb.	—	—	1 10	1 20
Alcohol, Ethyl.....gal.	—	—	4 65	5 00
Alcohol, Methyl (see methanol).....gal.	—	—	—	—
Alcohol, denatured, 188 proof.....gal.	—	—	.37	.38
Alcohol, denatured, 190 proof.....gal.	—	—	.35	.36
Alum, ammonia, lump.....lb.	.03½	.03½	.04	.04½
Alum, potash, lump.....lb.	.03½	.04	.04½	.04½
Alum, chrome lump.....lb.	.08½	.08½	.08½	.09
Aluminum sulphate, commercial.....lb.	.01½	.02	.02½	.02½
Aluminum sulphate, iron free.....lb.	.02½	.03	.03½	.03½
Aqua ammonia, 26 deg., drums(750 lb.) lb.	.07½	.07½	.08	.08½
Ammonia, anhydrous, cyl.(100-150 lb.) lb.	.31	.32	.33	.35
Ammonium carbonate, powder.....lb.	.07	.07½	.08	.09
Ammonium chloride, granular (white sal ammoniac).....lb.	.07	.07½	.07½	.07½
Ammonium chloride, granular (gray sal ammoniac).....lb.	.07	.07½	.07½	.07½
Ammonium nitrate.....lb.	.07½	.07½	.07½	.08½
Amylacetate tech.....gal.	—	—	2 40	2 65
Arsenic oxide, (white arsenic) powdered lb.	.06½	.06½	.06½	.07
Arsenic, sulphide, powdered (red arsenic) lb.	.11½	.12	.12½	.13
Barium chloride.....ton	46 00	48 00	49 00	55 00
Barium dioxide (peroxide).....lb.	.20	.21	.22	.23
Barium nitrate.....lb.	.06½	.07	.07½	.08
Barium sulphate (precip.) (blanc fixe) lb.	.04	.04½	.04½	.05
Bleaching powder (see calc. hypochlorite).....lb.	—	—	—	—
Blue vitriol (see copper sulphate).....lb.	—	—	—	—
Borax (see sodium borate).....lb.	—	—	—	—
Brimstone (see sulphur, roll).....lb.	—	—	—	—
Bromine.....lb.	.27	.28	.28½	.30
Calcium acetate.....100 lbs.	1 75	2 00	—	—
Calcium carbide.....lb.	.04½	.04½	.05	.05½
Calcium chloride, fused, lump.....ton	23 50	24 00	24 50	25 50
Calcium chloride, granulated.....lb.	.01½	.02	.02½	.02½
Calcium hypochloride(bleach'g powder) 100 lb.	2 25	2 30	2 35	3 00
Calcium peroxide.....lb.	—	—	1 40	1 50
Calcium phosphate, tribasic.....lb.	—	—	.15	.16
Camphor.....lb.	—	—	.91	.95
Carbon bisulphide.....lb.	.06½	.06½	.07	.07½
Carbon tetrachloride, drums.....lb.	.10½	.10½	.11	.12
Carbonyl chloride, (phosgene).....lb.	—	—	.60	.75
Caustic potash (see potassium hydroxide).....lb.	—	—	—	—
Caustic soda (see sodium hydroxide).....lb.	—	—	—	—
Chlorine, gas, liquid-cylinders(100 lb.) lb.	.08	.09	.09½	.10
Chloroform.....lb.	—	—	.40	.43
Cobalt oxide.....lb.	—	—	2 00	2 10
Copperas (see iron sulphate).....lb.	—	—	—	—
Copper carbonate, green precipitate.....lb.	.19	.19½	.20	.21
Copper cyanide.....lb.	—	—	.50	.62
Copper sulphate, crystals.....lb.	.05½	.05½	.05½	.06
Cremon of tartar(see potassium bitartrate).....lb.	—	—	—	—
Epsom salt (see magnesium sulphate).....lb.	—	—	—	—
Ethyl Acetate Com. 85%.....gal.	—	—	.70	.80
Ethyl Acetate pure (acetic ether, 98% to 100%).....gal.	—	—	.95	—
Formaldehyde, 40 per cent.....lb.	.11	.11½	.11½	.12½
Fusel oil, ref.....gal.	—	—	2 50	3 00
Fusel oil, crude.....gal.	—	—	1 50	1 75
Glauber's salt (see sodium sulphate).....lb.	—	—	—	—
Glycerine, C. P. drums extra.....lb.	—	—	.14½	.15
Iodine, resublimed.....lb.	—	—	3 50	3 60
Iron oxide, red.....lb.	—	—	.12	.18
Iron sulphate (copperas).....ton	18 00	19 00	20 00	23 00
Lead acetate.....lb.	—	—	.10½	.12½
Lead arsenate, powd.....lb.	.15	.15½	.15½	.16½
Lead nitrate.....lb.	—	—	.15	.20
Litharge.....lb.	.08	.08½	.08½	.09
Lithium carbonate.....lb.	—	—	1 40	1 50
Magnesium carbonate, technical.....lb.	.08	.08½	.09	.10
Magnesium sulphate, U. S. P.....100 lb.	2 50	2 75	—	—
Magnesium sulphate, technical.....100 lb.	—	—	1 10	1 75
Methanol, 95%.....gal.	—	—	.66	.68
Methanol, 97%.....gal.	—	—	.70	.72
Nickel salt, double.....lb.	—	—	.12	.12½
Nickel salt, single.....lb.	—	—	.14	.14½
Phosgene (see carbonyl chloride).....lb.	—	—	—	—
Phosphorus, red.....lb.	.40	.41	.42	.45
Phosphorus, yellow.....lb.	—	—	.30	.35
Potassium bichromate.....lb.	.11	.11½	.11½	.12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . - \$. . .	\$0.28 - \$0.30
Potassium bromide, granular..... lb.		.15 - .20
Potassium carbonate, U. S. P..... lb.	.15 - .16	.17 - .20
Potassium carbonate, 80-85%..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{1}{2}$	.05 - .06
Potassium chlorate, crystals..... lb.	.05 $\frac{1}{2}$ - .06	.06 $\frac{1}{2}$ - .12
Potassium cyanide..... lb.		.40 - .45
Potassium hydroxide (caustic potash)..... lb.	.05 $\frac{1}{2}$ - .06	.06 $\frac{1}{2}$ - .08
Potassium iodide..... lb.		2.60 - 2.75
Potassium nitrate..... lb.	.07 $\frac{1}{2}$ - .07 $\frac{1}{2}$	.08 - .09
Potassium permanganate..... lb.	.17 - .18	.18 $\frac{1}{2}$ - .21
Potassium prussiate, red..... lb.	.28 - .29	.29 $\frac{1}{2}$ - .30
Potassium prussiate, yellow..... lb.	.21 - .21 $\frac{1}{2}$	.21 $\frac{1}{2}$ - .22
Rochelle salts (see sodium potas. tartrate)		
Salammoniac (see ammonium chloride)		
Salsoda (see sodium carbonate)		
Salt cake (bulk)..... ton		20.00 - 22.00
Silver cyanide..... oz.		1.10 - 1.20
Silver nitrate..... oz.		.45 - .46
Soda ash, light..... 100 lb.	2.00 - 2.10	2.15 - 2.50
Soda ash, dense..... 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate..... lb.	.04 - .04 $\frac{1}{2}$	.04 $\frac{1}{2}$ - .05
Sodium bicarbonate..... 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium bichromate..... lb.	.08 - .08 $\frac{1}{2}$	.08 $\frac{1}{2}$ - .08 $\frac{3}{4}$
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.04 $\frac{1}{2}$ - .05	.05 $\frac{1}{2}$ - .06
Sodium borate (borax)..... lb.	.05 $\frac{1}{2}$ - .06	.06 $\frac{1}{2}$ - .07
Sodium carbonate (sal soda)..... 100 lb.	1.80 - 1.90	2.00 - 2.20
Sodium chlorate..... lb.	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$	.08 - .08 $\frac{1}{2}$
Sodium cyanide..... lb.	.28 - .28 $\frac{1}{2}$	.29 - .30
Sodium fluoride..... lb.	.11 - .12	.12 $\frac{1}{2}$ - .14
Sodium hydroxide (caustic soda)..... 100 lb.	4.00 - 4.10	4.15 - 4.50
Sodium hyposulphite..... lb.		.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$
Sodium nitrite..... lb.	.06 $\frac{1}{2}$ - .07	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$	.04 $\frac{3}{4}$ - .05 $\frac{1}{2}$
Sodium potassium tartrate (Rochelle salts) lb.		.21 - .24
Sodium prussiate, yellow..... lb.	.14 $\frac{1}{2}$ - .14 $\frac{3}{4}$	.15 - .15 $\frac{1}{2}$
Sodium silicate, solution (40 deg.)..... 100 lb.	.95 - 1.00	1.10 - 1.25
Sodium silicate, solution (60 deg.)..... 100 lb.	2.30 - 2.40	2.45 - 3.00
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$	.05 - .05 $\frac{1}{2}$
Sodium sulphite, crystals..... lb.	.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$	.04 - .04 $\frac{1}{2}$
Strontium nitrate, powdered..... lb.	.13 - .14	.14 $\frac{1}{2}$ - .20
Sulphur chloride, red..... lb.	.06 - .06 $\frac{1}{2}$	.06 $\frac{1}{2}$ - .07
Sulphur, crude..... ton	18.00 - 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08 $\frac{1}{2}$	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride..... lb.	.09 - .09 $\frac{1}{2}$	.09 $\frac{1}{2}$ - .10
Tin oxide..... lb.		.37 - .38 $\frac{1}{2}$
Zinc carbonate, precipitate..... lb.	.16 - .16 $\frac{1}{2}$	.17 - .17 $\frac{1}{2}$
Zinc chloride, gran..... lb.	.09 - .09 $\frac{1}{2}$	.09 $\frac{1}{2}$ - .10
Zinc cyanide..... lb.	.42 - .44	.45 - .47
Zinc dust..... lb.	.11 $\frac{1}{2}$ - .11 $\frac{3}{4}$	.11 $\frac{3}{4}$ - .12 $\frac{1}{2}$
Zinc oxide, XX..... lb.	.07 $\frac{1}{2}$ - .07 $\frac{3}{4}$	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.30 - .32
Aniline oil, drums extra..... lb.	.18 - .20
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.35 - 1.45
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.62 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.75 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.30 - .34
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.15 - .16
Ortho-cresol, in drums (100 lb.)..... lb.	.24 - .26
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.00 - 1.10
Dimethylaniline..... lb.	.45 - .60
Dinitrobenzene..... lb.	.23 - .27
Dinitrochlorobenzene..... lb.	.20 - .25
Dinitronaphthalene..... lb.	.30 - .35
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, car lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.00 - 1.10
Meta-phenylenediamine..... lb.	1.10 - 1.15
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.65 - 1.70
Naphthalene crushed, in bbls..... lb.	.06 $\frac{1}{2}$ - .08
Naphthalene, flake..... lb.	.06 $\frac{1}{2}$ - .08
Naphthalene, balls..... lb.	.08 - .09 $\frac{1}{2}$
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80
Para-dichlorobenzene..... lb.	.12 - .15
Paranitroaniline..... lb.	.75 - .80
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.40 - .50

Phenol, U. S. P., drums..... lb.	.10 - .12
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.00 - 2.25
Salicylic acid, tech., in bbls..... lb.	.20 - .21
Salicylic acid, U. S. P..... lb.	.22 - .23
Salol..... lb.	.70 - .72
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .48
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .33

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.20 - \$0.21
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.34 - .38
Candellilla wax..... lb.	.24 - .24 $\frac{1}{2}$
Carnauba, No. 1..... lb.	.45 - .46
Carnauba, No. 2, North Country..... lb.	.23 - .23 $\frac{1}{2}$
Carnauba, No. 3, North Country..... lb.	.14 - .14 $\frac{1}{2}$
Japan..... lb.	.21 - .21 $\frac{1}{2}$
Montan, crude..... lb.	.04 - .04 $\frac{1}{2}$
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.03 $\frac{1}{2}$ - .03 $\frac{3}{4}$
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 - .04 $\frac{1}{2}$
Paraffine waxes, refined, 125 m.p..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 $\frac{1}{2}$ - .04 $\frac{3}{4}$
Paraffine waxes, refined, 133-135 m.p..... lb.	.05 $\frac{1}{2}$ - .05 $\frac{3}{4}$
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 $\frac{1}{2}$ - .06
Stearic acid, single pressed..... lb.	.09 $\frac{1}{2}$ - .09 $\frac{3}{4}$
Stearic acid, double pressed..... lb.	.09 $\frac{1}{2}$ - .09 $\frac{3}{4}$
Stearic acid, triple pressed..... lb.	.10 $\frac{1}{2}$ - .10 $\frac{3}{4}$

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.60 - 5.60
Rosin E-I..... 280 lb.	5.65 - 5.70
Rosin K-N..... 280 lb.	6.25 - 6.80
Rosin W. G.-W. W..... 280 lb.	7.00 - 7.25
Wood rosin, bbl..... 280 lb.	6.25 -
Spirits of turpentine..... gal.	.80 -
Wood turpentine, steam dist..... gal.	.78 -
Wood turpentine, dest. dist..... gal.	.76 -
Pine tar pitch, bbl..... 200 lb.	 - 6.00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	 - 10.50
Retort tar, bbl..... 500 lb.	 - 10.50
Rosin oil, first run..... gal.	.36 -
Rosin oil, second run..... gal.	.39 -
Rosin oil, third run..... gal.	.46 -
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.90 -
Pine oil, pure, dest. dist..... gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 -
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25 -
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 -
Pinewood creosote, ref..... gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 -
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 -
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 -
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 -

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.60 - 2.90
Blood, dried, f.o.b., N. Y..... unit	4.00 -
Bone, 3 and 50, ground, raw..... ton	30.00 - 32.00
Cyanamide, f.o.b. works..... unit	4.50 -
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 - 3.00
Nitrate soda..... 100 lb.	2.40 - 2.45
Tankage, high grade, f.o.b. Chicago..... unit	2.75 - 3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 - 6.50
Tennessee, 78-80 p.c..... ton	8.50 - 9.00
Potassium muriate, 80 p.c..... ton	37.00 - 40.00
Potassium sulphate..... unit	1.00 - 1.10

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 $\frac{1}{2}$ - .22 $\frac{1}{2}$
Upriver coarse..... lb.	.13 $\frac{1}{2}$ - .14
Upriver caucho ball..... lb.	.13 - .13 $\frac{1}{2}$
Plantation—First latex crepe..... lb.	.17 $\frac{1}{2}$ - .18
Ribbed smoked sheets..... lb.	.17 $\frac{1}{2}$ - .18
Brown crepe, thin, clean..... lb.	.15 -
Amber crepe No. 1..... lb.	.17 $\frac{1}{2}$ -

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 $\frac{1}{2}$ - \$0.10 $\frac{1}{2}$
Castor oil, AA, in bbls..... lb.	.11 $\frac{1}{2}$ - .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 - .13 $\frac{1}{2}$
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .09 $\frac{1}{2}$
Cocoonut oil, Cochinchina grade, in bbls..... lb.	.10 - .10 $\frac{1}{2}$
Corn oil, crude, in bbls..... lb.	.09 - .09 $\frac{1}{2}$
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 - .07 $\frac{1}{2}$
Cottonseed oil, summer yellow..... lb.	.08 $\frac{1}{2}$ - .09
Cottonseed oil, winter yellow..... lb.	.09 $\frac{1}{2}$ - .09 $\frac{3}{4}$

Linseed oil, raw, ear lots (domestic)..... gal.	.65	—	.66
Linseed oil, raw, tank cars (domestic)..... gal.	.60	—	.61
Linseed oil, in 5-bbl lots (domestic)..... gal.	.68	—	.69
Olive oil, Denatured..... gal.	\$1.15	—	\$1.20
Palm, Lagos..... lb.	.07 $\frac{1}{2}$	—	.08
Palm, Niger..... lb.	.06 $\frac{1}{2}$	—	.06 $\frac{1}{2}$
Peanut oil, crude, tank cars (f.o.b. mill)..... lb.	.08	—	.08 $\frac{1}{2}$
Peanut oil, refined, in bbls..... lb.	.11 $\frac{1}{2}$	—	.11 $\frac{1}{2}$
Rapeseed oil, refined in bbls..... gal.	.83	—	.84

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

MOBILE—The United States Turpentine & Rosin Co., organized with a capital of \$1,250,000, Frank W. Boynton, president, has preliminary plans under way for the establishment of a new plant at Crichton, Ala., for the manufacture of turpentine, rosin and affiliated products. The machinery installation will include crushing equipment, retorts, distilling apparatus, etc.

MOBILE—The International Cotton Protecting Co. has plans under way for the construction of a local plant for the manufacture of special raw cotton preservatives. Work will be commenced at an early date.

Georgia

ELBERTON—Fire, Nov. 9, destroyed a portion of the plant of the Elberton Cotton Oil Co., with loss estimated in excess of \$40,000, including equipment. The plant will be rebuilt.

ATLANTA—The Diamond Holfast Rubber Co. has awarded a contract to the Griffin Construction Co., for the erection of its proposed local plant, estimated to cost about \$25,000. A. Ten Eyck Brown, Forsyth Bldg., is architect.

Louisiana

CEDAR GROVE—The Shreveport Lamp Chimney Co., has preliminary plans under way for the erection of an addition to its local plant, to include the installation of new machinery. Thomas F. McBride, Salem, W. Va., is president of the company.

Maryland

BALTIMORE—The McHenry-Millhouse Mfg. Co., South Bend, Ind., is planning for early operations at the local plant of the Electrolytic Zinc Co., 1200 South 16th St., recently acquired, to be used for the manufacture of coating paints and compounds for roofing service, asphalt roofing specialties, etc. The building will be remodeled and enlarged, and necessary machinery installed. J. L. Kittinger is general manager.

BALTIMORE—The Spanish-American Cork Products Co. has acquired the plant and business of the Spanish-American Cork & Specialty Co., with works at Westport, near Baltimore, and in the future will operate at this location. The former factory of the company, recently destroyed by fire, will not be rebuilt at the present time. Plans are under way for expansion at the Westport plant to cost about \$150,000, with proposed machinery installation for the manufacture of cork automobile accessories to represent an investment of close to \$50,000. Oscar T. Harms is president, and Oscar L. Swope, treasurer.

Massachusetts

SPRINGFIELD—Flink & Olson, 518 Page Blvd., have had plans prepared for the erection of a 1-story foundry, 32 x 60 ft. Stuart & Tessler, 94 State St., are architects.

Michigan

PORT HURON—Contract for the new addition to be erected at the plant of the Port Huron Sulphite & Paper Co., has been awarded to Alfred J. O'Sullivan, Port Huron. It will be 2-story and basement, 70 x 100 ft., located on Black River St., with estimated cost of about \$150,000, including machinery. Walter Wythe, 509 Chestnut Ave., is architect.

THREE RIVERS—The Eddy Paper Co. is reported to be considering the construction of two new manufacturing units at its plant, estimated to cost in excess of \$5,000,000. H. L. Vanderherst is vice-president.

BLACK CREEK—The Outagamie Limestone Co., 75 Thirtieth St., Milwaukee, Wis., is perfecting plans for the erection of a new limestone plant in the vicinity of Black Creek, estimated to cost about \$200,000 with

machinery. H. O. Weldon, 10 South La Salle St., Chicago, Ill., is engineer.

KALAMAZOO—The King Paper Co. and the Monarch Paper Co., both of Kalamazoo, with the Bardeen Paper Co., Otsego, Mich., have been consolidated under the name of the Allied Paper Mills, capitalized at \$6,000,000. The different mills of the merged company include 10 paper machines and 3 coating mills, giving employment to over 1,400 operatives under normal production. It is proposed to acquire, by control or purchase, a pulp mill to insure a supply of bleached pulp for production. A general expansion in plant facilities is planned. A. L. Pratt, heretofore head of the King Paper Co., is president of the new corporation.

Minnesota

MINNEAPOLIS—The Minnesota Mfg. Co., 722 North Third St., manufacturer of chemical compounds, etc., has rejected bids received for the construction of its proposed 3-story plant on Eighth Ave., and will call for new bids early in the coming spring. The factory is estimated to cost about \$35,000. E. J. Miller is secretary.

Missouri

ST. LOUIS—The General Mfg. Co., Eighteenth and Pine Sts., has leased a 2-story building in the vicinity of its works, and will establish a plant for the manufacture of rubber specialties, leather belting, etc. The structure will be remodeled and improved to accommodate the industry.

CAPE GIRARDEAU—The National Mining Co. has acquired a local site and is said to have plans in preparation for the erection of a new silica refining plant, estimated to cost in excess of \$75,000.

Montana

GREAT FALLS—The American Refining Co., Okmulgee, Okla., is planning for the construction of a new oil refinery at Great Falls, to utilize crude oil production from the Cat Creek district.

New Jersey

WOODBIDGE—Fire, Nov. 14, destroyed the plant of the Sepoy Chemical Co., Edgar's Station, near Woodbridge, with loss estimated at about \$60,000. The factory was used for the manufacture of dyes, colors and kindred chemical products.

DOVER—The Thomas Iron Co. has commenced excavations for the construction of an addition to its concentrating mill at the Richard Mine, near Dover. The extension, with machinery, is expected to increase the present output of 4,000 tons of ore per month to more than 20,000 tons. A new crushing process will be adopted at the plant.

TRENTON—The Nottingham Rubber Co., 150 East State St., recently organized with a capital of \$500,000, has obtained options on a tract of land near Philadelphia, Pa., as a site for the erection of its proposed new plant for the manufacture of rubber products, including a patented puncture-proof inner tube for automobile tires. Preliminary plans for the factory are under way and it is said that erection will be commenced at an early date. The company is headed by C. Francis Fisk and Samuel H. Bell.

New York

HUDSON—The International Cement Co. has awarded a contract to the Turner Construction Co., 244 Madison Ave., New York, for the erection of a 1-story building at its local plant, 160 x 600 ft., estimated to cost about \$200,000. Excavation work will be placed under way at once.

LONG ISLAND CITY—The Grasselli Chemical Co., Independence Road, Cleveland, O., has filed plans for the erection of a 1-story building at its local plant, 80 x 250 ft., at Morgan St. and Montrose Ave. The Barney Ahlers Co., 110 West Fortieth St., New York, has the construction contract.

Ohio

ASHLAND—The Dragon Rubber Co., North Galloway St., is considering the erection of an addition to its plant.

SANDUSKY—The Farrell-Cheek Steel Foundry Co., has construction under way on a 1-story plant addition, 90 x 180 ft., and plans for early occupancy. Herbert Farrell is president.

MARBLEHEAD—The Kelly Island Lime & Transport Co., Leader-News Bldg., Cleveland, O., has commenced the erection of the steel work for its new local crushing plant, to be 60 x 60 ft., and 170 ft. high, and plans to have the structure ready for the machinery installation at an early date.

Oregon

PORTLAND—The Shope Brick Co., manufacturer of cement brick products, has received a contract for the erection of a plant for the Chinese Government at Canton, China, to be equipped for an initial production of about 125,000 bricks per day. Machinery will be constructed and transported to the site in the near future. D. F. Shope is president.

Pennsylvania

NEW CASTLE—F. A. Seiberling, former president of the Goodyear Tire & Rubber Co. and now operating a local plant under the name of the Lehigh Tire & Rubber Co., has organized a new company under Delaware laws, to be known as the Seiberling Rubber Co., capitalized at \$55,000,000, to manufacture tires and other rubber products. Arrangements have been perfected for the purchase of the plant and business of the Portage Tire & Rubber Co., operating under a receivership for a number of months past, for a consideration said to be close to \$1,000,000. This plant will be operated in conjunction with the New Castle works, representing two manufacturing units of the new Seiberling Co.

PITTSBURGH—The Aluminum Co. of America, Oliver Bldg., has tentative plans under way for the construction of a new hydro-electric power plant in the vicinity of Long Sault Rapids, N. Y., to be used for works operating service in this district. F. S. Fickes, company address, is engineer.

SHIPPENPORT—Fire, Nov. 16, destroyed a portion of the local oil works of the Southwest Pennsylvania Pipe Lines Co., a subsidiary of the Standard Oil Co., with loss estimated at about \$35,000.

PITTSBURGH—The Standard Envelope Mfg. Co. has leased space in the new Chatfield & Woods Bldg., Second Ave. and Short St., for expansion.

LANCASTER—The Armstrong Cork Co. has construction under way on a 1-story shop addition at its local plant, 25 x 35 ft., at Liberty and Mary Sts.

PHILADELPHIA—The Metzger Co., Fifth and Federal Sts., glass products, has filed plans for the erection of a 3-story plant addition, 35 x 68 ft., to cost about \$17,000.

Tennessee

CHATTANOOGA—The new works to be constructed by the Ocoee Copper Co., 1135 Volunteer Life Bldg., at Ducktown, Tenn., will include an extensive flotation plant for the treating of copper ores. The entire works will cost about \$200,000. J. I. Carter is president.

Texas

WACO—The Morris Oil Refining Co. has commenced preliminary production at its new refinery at South Bosque, near Waco, and proposes to develop a capacity of about 1,000 bbl. a day. R. E. Whitlock is manager.

CISCO—Homer Peeples, operating in the Callahan field, near Cisco, has plans under way for the construction of a new casing-head gasoline plant to serve the different properties in this district.

West Virginia

WESTON—The Interstate Window Glass Co. is planning for the rebuilding of its local plant, recently partly destroyed by fire, with loss estimated at about \$25,000.

Canada

BRITANNIA BEACH, B. C.—The Britannia Mining & Smelting Co. is planning for the early rebuilding of its smelting works, recently damaged by flood, and has awarded a contract to the Traylor Engineering & Mfg. Co., Allentown, Pa., for the construction of 18 large tube mills and 5 sets of crushing rolls, the largest to be 72 in. in diameter. The machinery is expected to be ready for shipment in about 90 days.

New Publications

Industrial India is the title of a new monthly magazine published for distribution among the industries of India by the Tata Publicity Corp., Ltd., London. This is the first attempt to produce a modern industrial magazine for India, and the publication should be of interest to those who are developing the Indian market.

THE IMPERIAL MINERAL RESOURCES BUREAU, London, England, has published the following bulletins, on Talc: Fluorspar; Coal, Coke and Byproducts; Tungsten and Manganese.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: Mineral Resources of the U. S. in 1920 (Preliminary Summary); I:1, Cadmium in 1920, by C. E. Siebenthal and A. Stoll (Mineral Resources of the U. S., 1920, Part I), published May 12, 1921; I:2, Gold, Silver, Copper, Lead and Zinc in the Eastern States in 1920, by J. P. Dunlop (Mineral Resources of the U. S., 1920, Part I), published Aug. 13, 1921; I:4, Chromite in 1920, by Edward Sampson (Mineral Resources of the U. S., 1920, Part I), published Aug. 17, 1921; I:5, Bauxite and Aluminum in 1920, by James M. Hill (Mineral Resources of the U. S., 1920, Part I), published Aug. 31, 1921; I:6, Platinum and Allied Metals in 1920, by James M. Hill (Mineral Resources of the U. S., 1920, Part I), published Sept. 9, 1921; I:7, Arsenic, Bismuth, Selenium and Tellurium in 1920, by Victor C. Heikes (Mineral Resources of the U. S., 1920, Part I), published Sept. 22, 1921; I:13, Silver, Copper, Lead and Zinc in the Central States in 1919, by J. P. Dunlop (Mineral Resources of the U. S., 1919, Part I), published May 25, 1921; I:16, Gold, Silver, Copper, Lead and Zinc in Arizona in 1919, by V. C. Heikes (Mineral Resources of the U. S., 1919, Part I), published Aug. 12, 1921; I:17, Gold, Silver, Copper, Lead and Zinc in Nevada in 1919, by V. C. Heikes (Mineral Resources of the U. S., 1919, Part I), published Aug. 16, 1921; I:18, Gold, Silver, Copper, Lead and Zinc in Utah in 1919, by V. C. Heikes (Mineral Resources of the U. S., 1919, Part I), published Aug. 9, 1921; I:19, Gold, Silver, Copper, Lead and Zinc and Idaho and Washington in 1919, by C. N. Gerry (Mineral Resources of the U. S., 1919, Part I), published Aug. 11, 1921; I:20, Gold, Silver, Copper, Lead and Zinc in Montana in 1919, by C. N. Gerry (Mineral Resources of the U. S., 1919, Part I), published Aug. 17, 1921; I:21, Copper in 1919, by H. A. C. Jenison (Mineral Resources of the U. S., 1919, Part I), published Sept. 8, 1921; I:31, Zinc in 1918, by C. E. Siebenthal (Mineral Resources of the U. S., 1918, Part I), published April 29, 1921; I:B, Mineral Resources of the United States in 1918, Introduction by Edson S. Bastin, summary by Martha B. Clark (Mineral Resources of the U. S., 1918, Part I), published Aug. 15, 1921; II:1, Magnesite in 1920 by Charles G. Yale and Ralph W. Stone (Mineral Resources of the U. S., 1920, Part II), published July 27, 1921; II:2, Salt, Bromine and Calcium Chloride in 1920 by Ralph W. Stone (Mineral Resources of the U. S., 1919, Part II), published July 20, 1921; II:27, Feldspar in 1919, by L. M. Beach (Mineral Resources of the U. S., 1919, Part II), published Aug. 12, 1921; II:30, Cement in 1919, by Ernest F. Burchard (Mineral Resources of the U. S., 1919, Part II), published Sept. 21, 1921.

THE MOSSBACHER CO., New York, N. Y., has been incorporated with a nominal capital of \$5,000, to manufacture chemicals and chemical byproducts. The incorporators are R. and J. Kraus, and S. S. Mossbacher, New York. The company is represented by Max Silverstein, 309 Broadway.

New Companies

THE VERA CHEMICAL CO., Stoneham, Mass., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. Wilfred H. Smart is president; and Peter F. McCarty, 8 Winter St., Boston, Mass., treasurer.

THE STRAITS RUBBER CO., Detroit, Mich., has been incorporated with a capital of \$20,000, to manufacture rubber products. The incorporators are A. E. Severance, K. H. and E. R. Glanton, 3765 Philadelphia St., West, Detroit.

THE ANALGOL CHEMICAL CO., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are M. and A. Saracena, and Luigi Miscione, 291 Broadway, New York.

THE CELLULOSE CORP., Newark, N. J., has been incorporated with a capital of \$5,000, to manufacture cellulose specialties, celluloid products, etc. The incorporators are Eugene Berry, E. Moore and John C. Waserbach, 78 Park St., Newark.

THE TITAN ABRASIVES CO., Room 610, 139 North Clark St., Chicago, has been incorporated with a capital of \$10,000, to manufacture abrasive products. The incorporators are Roland R. Hurford, A. B. Singleman and Albert J. Doermann.

FRED STERN & CO., INC., New York, has been incorporated with a capital of \$1,000,000, to manufacture rubber products, gutta percha specialties, etc. The incorporators are Fred Stern, J. S. Kane and L. H. Heyworth. Offices of the company are at 277 Broadway.

THE KEYSTONE CARBONIC GAS CO., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of \$2,000,000, to manufacture carbonic acid gas and kindred products. The incorporators are S. S. Bailey, Pittsburgh; J. H. Loller and T. B. Donnelly, Connellsville, Pa. The company is represented by the Capital Trust Co., Dover, Del.

THE TEMPLE COTTON OIL CO., Hope, Ark., has been incorporated with a capital of \$1,000,000, to manufacture cotton oil and affiliated products. H. A. Carpenter is president; F. O. Colleman, vice-president; and R. L. White, secretary and treasurer, all of Hope.

THE NORTH AMERICAN RUBBER CORP., 508 Union Bank Bldg., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture rubber products. The incorporators are L. E. Kraft, C. W. Brelsford and John C. Brown.

THE ECLIPSE MFG. CO., Pawtucket, R. I., has been incorporated with a capital of \$25,000, to manufacture polishes, paste, and kindred specialties. The incorporators are William H. Gough, Arthur Mellor and John W. Hadfield, 191 East Ave., Pawtucket.

THE AMERICAN NATIONAL PETROLEUM CO., New York, N. Y., has been incorporated with a capital of \$4,000,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE CYRUS CHEMICAL CO., South River, N. J., has been incorporated with a capital of \$20,000, to manufacture chemicals and chemical byproducts. The incorporators are James R. McCoy, A. L. Giles and Cyrus Butler, South River.

THE SOUTH FLORIDA OIL CO., Tampa, Fla., has been incorporated with a capital of \$50,000, to manufacture oil products. Earl H. McRae is president; John A. Gallagher, vice-president; and Edward A. Kitchen, secretary and treasurer, all of Tampa.

THE SCRANTON COLOR & CHEMICAL CO., Scranton, Pa., has been incorporated under

Delaware laws with capital of \$100,000, to manufacture chemicals and affiliated products. The company is represented by the Corporation Service Co., Wilmington, Del.

THE PORCELIZED METAL CO., Buffalo, N. Y., has been incorporated with a capital of \$150,000, to manufacture special porcelain compounded metal products. The incorporators are J. B. Devine and A. B. Taylor. The company is represented by D. F. Strebel, Marine Bank Bldg., Buffalo.

THE LONG-WEAR TIRE & RUBBER CO., Anderson, Ind., has been incorporated with a capital of \$300,000, to manufacture tires and other rubber products. The incorporators are B. B. Benner, Albert Anderson, Ernest Bond, and Nathan Ridgway, all of Anderson.

THE PITTMAN CHEMICAL CO., Birmingham, Ala., has been organized under state laws to manufacture chemicals and chemical byproducts. F. M. Pittman is president and general manager; R. L. Lange, vice-president; and M. I. Pittman, secretary, all of Birmingham.

THE PARAFLEX RUBBER CORP., New York, N. Y., has been incorporated with a capital of \$30,000, to manufacture rubber products of various kinds. The incorporators are A. W. Palmer and V. A. Roberts. The company is represented by Merrell, Bates & Topping, 27 Cedar St., New York.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 27 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Emerson Hotel.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN PETROLEUM INSTITUTE will hold its second annual meeting at the Congress Hotel, Chicago, Dec. 6, 7 and 8.

COLLEGE OF THE CITY OF NEW YORK, department of chemistry, will give public lectures under the auspices of the City College Chemical Society in the Doremus Lecture Theater, at 4:30 p.m., as follows: Nov. 30, "Afterthoughts of the War," by Leland L. Summers, of the War Industries Board; Dec. 6, "America in Chemistry," by Dr. Edgar F. Smith, provost emeritus, University of Pennsylvania, and president, American Chemical Society.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting; Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Land Armaments

And Business Recovery

BRUSHING aside the academic and partisan contention that the United States should keep out of European affairs, we believe it is growing clear that we are no longer confronted with the problem of whether we should keep out or get in, but rather of how much deeper we must get in before we can fairly get out. Whether we like it or not and whether it conforms to sonorous platitudes glibly quoted, the fact remains that the economic welfare of the United States is inextricably bound up with that of Europe. Splendid isolation will avail us nothing in efforts to bring about the desired revival of business.

Let us see if we can clarify the situation in a few words. Admitting that foreign trade is not essential to some of our industries, nevertheless there are others of fundamental importance like mining and agriculture that will not revive until foreign trade in considerable volume is again possible. Certainly the restoration of international trade in something like pre-war volume is a prerequisite to world prosperity. But it is idle to talk of developing foreign trade when the financial systems of Europe are crashing about our heads and when there is no stable basis on which to frame tariffs for future business.

Obviously there must be some logical and basic place to begin the rehabilitation of the world's economic and financial systems. Europe is more stable socially and politically than at any time since the Armistice. It is only in finance that there has been continued degradation. Money has depreciated because of inflation through printed currency. Printing presses have been kept busy because national expenditures have exceeded national income. Fiscal budgets have been unbalanced. And the curious coincidence about the fiscal deficits of the countries of central Europe is that they correspond almost exactly with the cost of maintaining land armaments in those countries. Four or five million men are under arms, including the Rhine army of 350,000 men with its tremendous cost to Germany contributing to her recognized inability to meet the reparations.

Have we not here the crux of the situation? If European land armaments could be greatly reduced and limited, fiscal budgets would be more nearly balanced. Inflation could cease. Exchange could then be stabilized and commerce could be resumed on a basis that could be depended upon to last over night. If the cost of maintaining land armaments is breaking down the financial systems of Europe and if that breakdown is being reflected in decreased buying power and unstable business conditions throughout the world, wouldn't it be wise to take steps to reduce land armaments? And might not the United States call an international conference for the purpose of considering land disarmament in Europe in its relation to worldwide economic and financial conditions?

Taking our cue from the present conference on naval disarmament and problems of the Far East, which gives every reasonable expectation of a successful issue, we think that a second conference might profitably be called at an early date to deal specially with economic and financial matters and the limitation of land armaments. The two are intimately related. The hopeful influence of such a conference cannot be overestimated. The mere announcement of the Hughes plan at the opening of the present conference caused a rise in all European exchange that could have been produced otherwise only by the movement of large quantities of goods. It increased confidence in world recovery, which is so greatly needed now. The calling of a second conference on economic conditions would likewise react favorably on world business.

It has been suggested that the present conference might consider this problem, but we are inclined to believe that it should be differently constituted. In addition to political representatives, such a conference should comprise men representing the great business interests and activities of the respective countries. The problems before such a conference would be essentially business problems, and as such should receive the attention of the best business minds. Probably no decisive steps can or should be taken to convene a new conference until the present one has had a successful outcome. But the call should be made as early as possible so that its stimulating first-aid influence can help sustain business until permanent stabilizing measures can be adopted.

We feel that we are not wrong in advocating the appointment of representatives of business and industry, capital and labor to a conference on economics and finance. Recent history affords ample evidence to support the contention that business leaders have long seen what political leaders have been either unwilling or unable to see with regard to the trend of economic affairs. Certainly the best views of the situation in Europe that have been laid before business in this country have come from American business men and bankers who have studied conditions at first hand.

Prevention of Tuberculosis

A Means of Increasing Business

SINCE the prevention of waste has become one of the cardinal principles of increasing production, any known means of eliminating waste of man power is a matter of vital interest. Prevention of tuberculosis unquestionably means a conservation of the human element in production, when it is known that this disease is responsible for one-third of all the deaths which occur in this country among persons between the ages of fifteen and forty-five years. In other words, tuberculosis strikes down man and woman alike during the period of their productive years.

The nature of tuberculosis is well known today and

numerous carefully conducted studies have demonstrated that its existence depends to a great extent upon conditions in which men work. There are, naturally, some particularly bad features about certain trades. Chief among these are the so-called dusty occupations, for dust inflames the air passages of the lungs and makes these passages liable to the disease. Not all dusts are dangerous, however, for coal dust apparently has no bad effect. Coal miners are even less likely than others to have the disease, and only one-third as many cases of tuberculosis appear among the coal miners in Pennsylvania as among other persons.

Of the workers showing a high mortality for tuberculosis, there are, first, the grinders, then tool makers, printers, stone cutters, brass workers, garment workers and furriers and all classes who are exposed to mineral and metal dusts. On the other hand, boot and shoe makers and millers have a very low mortality rate for this disease. In mining and the related industries the death rate from tuberculosis, with the exception of coal miners, is higher than for other work. This is particularly true of certain mining industries, such as copper, silver and lead mining. The reason for this is apparent, for metal mining is attended in most cases by the inhalation of particularly hard, sharp, flinty particles that find their way into the lungs and set up an irritation which makes fertile soil for the growth of the tuberculosis germ. Significant in this connection is the fact that out of the 44,000,000 men and women workers in the United States nearly 4,000,000, or 9.06 per cent, are employed in dusty trade industries and occupations.

That it pays to prevent tuberculosis in industries is well demonstrated in the experience of such large concerns as the New York Telephone Co., Metropolitan Life Insurance Co., Sears Roebuck Co., the International Harvester Co. and many others. The actual dollars and cents saved to these concerns as a result of health work aimed against tuberculosis has demonstrated the value and soundness of their investments along this line. It not only pays to prevent tuberculosis directly in industries but it pays also to prevent tuberculosis in the general population, of which the workers and employers alike are a part.

There is abundant evidence that any community can purchase a reasonable degree of freedom from tuberculosis if it is willing to pay the price. This price is not excessive, probably not more than \$2 per capita per year, spread over a period of 10, 15 or 20 years. Proper community organization can control disease, the extent of the control depending upon the intensiveness of organization. The annual December sale of tuberculosis Christmas seals furnishes the funds. Hence every person who buys Christmas seals is helping in a fight to conserve human life and therefore to prevent a waste of man power in business.

It is obvious that every person whose life is prolonged by the prevention of tuberculosis means increased wealth to the manufacturer and merchant because of the added working capacity of the individual. Nor is prevention a far away and hazy mirage. The fact is that the National Tuberculosis Association and its 1,200 affiliated agencies are fighting a winning war against tuberculosis. In the 15 years since the association began its work the death rate from tuberculosis in this country has been reduced from 200 per 100,000 population to the present figure of 120 per 100,000 population. This has been estimated to mean a clear saving of 75,000 lives a year.

New Propaganda For Old

A SPECIAL session of Congress has adjourned. Many of the legislators are at home, mending fences, and perhaps thereby getting clearer impressions of what their constituents think about it all. But they will immediately reassemble in regular session, and be engulfed in the whirl of politicians, lobbyists, patriots and well-meaning folk who clutter up the Capitol and increase the difficulty of doing the nation's business.

One of the important things yet to be done is to provide adequate protection for the chemical industry. It is not our present purpose to recount recent experiences proving that it is quite necessary for our country to have a well-developed chemical industry. That point is doubtless pretty well established. Nor is it desired to discuss various schemes which have been proposed, and all but enacted into law, for the fostering care of this essential industry. That ground has been covered at length many times. What we should like to emphasize is this—that whereas it is possible to present a convincing argument before congressional committees, and thus obtain a favorable report, it is and will be extremely difficult to get Congress as a whole to accept and act upon these reports. It naturally follows that success depends upon the ability to educate the Congressman hailing from the corn belt, who doesn't know much about chemistry except that a big bunch of nitrogen blew up recently in Germany, and the Senator living in a textile center who has been told that the American dye trust is a band of robbers.

We venture to express the opinion that friends of the industry would do well to emphasize the importance of chemistry to human progress and comfort, and to talk less about killing. Let's admit that chemistry has been introduced into warfare and we know very well that where science enters there it stays. We know, too, that with industry developed in organic chemistry, these factories are themselves arsenals of defense which cost the government nothing and can be quickly transformed to the production of the instruments of death and destruction.

But aren't we fed up on war and sick and tired of it? The minds of the civilized people of the whole world are against war. They have had more than enough! The gasp of incredulous joy which burst from every nation upon hearing Mr. HUGHES' disarmament proposals should entirely convince any but the stubbornest militarist that blood-curdling accounts of horribly dangerous poisons are no longer correct propaganda in support of the chemical industry.

Fortunately, machinery which can synthesize organic chemicals—like dyes, explosives, drugs, perfume and fabrics—are good for much else than for war. Otherwise, the chemical science and industry would not be worth saving, and we should be glad to help it along the path the battleship is taking. So, in abandoning the old arguments, there are new and cogent ones ready at hand which, instead of exciting fear and mistrust, light contentment and hope. A good anæsthetic or a specific for so mild a disease as measles would eventually save the future part of the woe the Hohenzollerns loosed upon the past. Not one, but a hundred, such discoveries are to be made in the future. And where, pray, will these be found if not by most advanced chemical research? In fact, only through this and its sister science physics can the process of life and the causes of death be anything but mystery. Here is common ground to

approach the corn-planter and the cotton-spinner, the miner and the fisherman.

We believe in the chemical industry because it is founded on truth, and its intensive development will promote our nation's economic health as will no other. That industry must be preserved and fostered because it will help every American to *live*, to live with more ease, more comfort, more safety, more health and joy. We believe in chemistry, because chemistry is life.

Speeding the Business Revival

EVEN in the chemical industry there is a widely prevalent feeling that "business is on the mend." This attitude on the part of our manufacturers augurs well for the future of business; it gives us a psychological advantage of real value. A year ago when trade began to fall from its post-war peaks, we started talking about business depression and hard times, we quit buying and very naturally business began to slump. In contrast with this pessimistic background, most of us at the present time are thinking in terms of business revival and are eagerly watching for signs of improvement and encouragement.

Obviously these signs will differ for the different industries and they will not carry the same significance to each of us. The iron and steel industry, for instance, has long held to the view that large-scale buying by the railroads was certain to herald the return of prosperity. This industry has recently had ample reason to be encouraged, for since the last week in October the railroads have been buying rails, locomotives, cars and other supplies on an increasingly heavy scale.

Most engineers regard new construction and the letting of building contracts as the most reliable index of business activity. It is heartening, therefore, to know that a building boom is sweeping the country. Contracts during October exceeded those in October, 1920, by 25 per cent and were only 10 per cent less than in the record month of September, 1921. One authority has reported the contracts for October to have reached \$222,500,000 and has pointed out that November's total promises to show a more striking increase. That the chemical and metallurgical industries are keeping pace with the building boom is shown by the following figures compiled from the Industrial Notes which appear weekly in this magazine:

	Total Cost			
	Oct.	Nov.	Oct.	Nov.
Projects planned...	34	43	\$11,338,000	\$26,353,000
Contracts awarded.	26	27	3,940,000	12,199,000

Construction on such a large scale means increased production of chemicals and a broadening market for chemical equipment, but, what is even more significant, it proves that chemical manufacturers are looking forward to the upward trend in business and are willing to make active preparations for it.

There is still another sign of encouragement which we are inclined to regard as the real proof that the wheels of industry are again in motion. In our news pages each week since Oct. 11 has been published an imposing list of industrial plants which have resumed operations or have materially increased their production. These give us incontrovertible evidence that manufacture is again under way and that the shut-down factories are gradually awakening from their period of lethargy. May the good work continue and may our weekly lists grow until they have included every plant in the chemical and metallurgical industries!

College Degrees For the Credulous

OUR excellent French contemporary *Chimie et Industrie* of Paris contains the following advertisement in its issue No. 4, Vol. 6, October, 1921:

Promotion de doctorat (par correspondance).
Université étrangère (U.S.A.) offic. reconnue.
Ecrire avec curric. vitæ à Prof. Demole, Case
Rhône 3373 Genève (Suisse).

They know better than that in France and they know better in Geneva. The acceptance of such an advertisement casts unfortunate reflections on all American university degrees. It belittles the academic honors lately bestowed on Field Marshal FOCH. We venture to state that there is no officially recognized university in the United States in which "Professor" DEMOLE of Geneva can arrange for doctorates in science or philosophy or letters or law, or in anything else, by correspondence.

It's curious how willing Europeans are to believe absurd things about the United States. To explain to credulous foreigners the customs of the country, the killings and shootings that make things interesting on the streets and to expound the unconventional ways of Indians and buffaloes constitute one of the few joys in life left to Americans. That sort of thing has become a habit with many of us, like killing sheep among dogs, because it is so easy. It is, however, an ancient sport. Sir JOHN MANDEVILLE was addicted to it back in the fourteenth century, as witness his description of the inhabitants of certain islands in his "Voyages and Travels."

And in another yle are foule men that have the lippes about the mouth so greate, that when they sleepe in the soone they cover theyr face with the lippe. And in another yle lyttle men, as dwarfes, and have no mouth but a lyttle round hole & through that hole they eate their meate with a pype, & they have no tongue, & they speake not, but they blow and whistle, & so make signes to one another. In Ethiopie are such men as have but one foote, and they go so fast yt is a great marvaill, and that is a large foote, that the shadow thereof covereth ye body from son or rayne. when they lye upon theyr backes; and when theyr children first be borne they loke like russet and when they waxe olde then they be all black.

The habit, it will be observed, is not even original with us Americans. But when foreigners imagine degree factories in the United States and proceed to fleece one another by selling false diplomas, it ceases to be innocent merriment. Thousands and thousands of young men and women come to our institutions of learning from all over the world, and they work hard for their degrees. They prize them highly. They stand for merit, just as French and Swiss and Italian and German degrees do. Of course, no one here can stop the precious DEMOLE from his misuse of foreign mails. But scientific and technological journals should not encourage the practice. The situation is very much as though we should publish an advertisement from somebody in Quebec offering to procure the decoration of the Legion of Honor for those who apply—and comply with his terms. It would be easy enough for him to fake up a diploma in French and to send a little red ribbon to his dupes—but it would not be ethical for us to help him. And we do not think it ethical for *Chimie et Industrie*, which is, generally speaking, an excellent paper, and for which we have a high regard, to permit DEMOLE to make use of its columns for his nefarious operations.

Readers' Views and Comments

Nitrogen in Carburized Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with the article appearing under the above title in CHEMICAL AND METALLURGICAL ENGINEERING, Nov. 9, 1921, page 867, it has just been called to our attention that no mention has been made of Fay's work in the same line, referred to in a note published in your journal in the issue of Feb. 16, 1921. The note referred to contains valuable analytical data having a very direct bearing in the subject under discussion in our paper, and promises later a full discussion of the entire subject, in which Dr. Fay has evidently been interested for some time. It is a matter of regret to the authors that such an important contribution should have been overlooked in the preparation of our paper.

What Causes Slip to Halt?

To the Editor of Chemical & Metallurgical Engineering

SIR:—In studying the Slip Interference Theory of the Hardening of Metals as first published in CHEMICAL & METALLURGICAL ENGINEERING, June 15, 1921, by Zay Jeffries and R. S. Archer, and in critically reviewing the older theories as well as discussions which have appeared relative to the new theory, this writer is unable to find a satisfactory explanation of the stopping of slip.

In a later paper entitled "The Amorphous Metal Hypothesis," published in CHEMICAL & METALLURGICAL ENGINEERING, Oct. 12, 1921, Jeffries and Archer ask the question, "What causes slip to halt?" There seems to be no better reason known at present than that originally offered by Beilby. Quoting from the paper by Jeffries and Archer on "The Slip Interference Theory of the Hardening of Metals," we find the following as an explanation for the stopping of slip:

The amorphous metal theory of Beilby offers what appears to the present authors to be the only completely satisfactory explanation of this phenomenon. The rubbing together of the crystal fragments on the plane of slip is supposed to tear some of the surface atoms loose from their regular crystalline arrangement, thus forming a layer of amorphous metal. The friction generates heat rapidly, so that a high temperature is reached locally. This high local temperature softens the amorphous metal, which is essentially merely an undercooled liquid. With the softening of the amorphous metal layer the resistance to slip diminishes and there is less frictional heat developed. The high local temperature is then quickly dissipated by conduction to the surrounding metal, whereupon the amorphous metal hardens and offers a resistance to further slip which is greater than that on planes on which slip has not yet occurred.

At this point let us look into the amorphous metal theory as proposed some years ago by Beilby. After reading carefully the last paragraph above quoted, it seems that there is not a satisfactory explanation given for the stopping of slip. The last sentence in the above paragraph appears to be the weak point. If amorphous metal is formed on the cleavage plane by friction and if friction generates heat enough to soften materially this amorphous metal so that slip occurs rather easily for a time, then as cooling begins the viscosity of this

amorphous metal increases, its resistance to slip increases, the heat of friction likewise increases and the tendency will be for a certain viscosity to be obtained such that its resistance to slip will create enough heat to equal the heat dissipated by conduction.

If conduction gets ahead for a time and the temperature momentarily drops, then the viscosity increases, the resistance to slip increases, the rate of generation of frictional heat will increase and at once build up the temperature to a point where the viscosity is lowered and a balance is obtained between heat generated and heat conducted away from the source of generation. If this proceeds, we should expect ultimate failure to occur along the cleavage plane of first slip. This, however, is not the case and the writer will presently endeavor to explain why. I certainly cannot conceive of the heat of friction being conducted away from the amorphous cement "instantly," as Beilby's theory indicates.

The time consumed from the beginning to the end of slip on any particular plane must indeed be quite small. It seems reasonable that the time required for conducting away the generated heat would be a large percentage of the total time of slip, even though it is only necessary for a portion of the total heat to be removed from the place where it is generated. There is no license to use the term "instantaneously," as Beilby says it, when speaking in relative terms, since this leads to the inference that the time required for conducting the heat away will be very short, or negligible, in comparison to the total time of slip. It seems that something else must take place to retard the rate of slip, which in turn will retard the rate of heat generation and by so doing give the amorphous metal opportunity to "set."

The following explanation is offered to account for the stopping of slip. Referring the strength of metals to the atomic bonds that oppose stresses working toward the deformation of the metal, it will be agreed that the elastic limit is determined by the maximum number of atomic bonds that simultaneously oppose the force that first tends to cause deformation. No other atomic bonds will ever come into full action in opposing tensile stresses until the elastic limit has been exceeded. As soon as the elastic limit has been exceeded slip occurs on some cleavage plane (or planes) containing the least number of active atomic bonds per unit area. Following Beilby, I assume amorphous cement to be formed on this plane and heat to be generated in amount sufficient to permit slip to take place freely. Slipping cannot go on very far, though, without additional atomic bonds being brought into action to oppose the slip in a manner similar to the way that after a few fibers in a rope under stress have given way, additional ones begin to be stressed so that their resistance must be overcome. In fact, this is in keeping with the statement of Jeffries and Archer that "The strengthening of metals by cold work can only be due to some mechanism by which the interatomic bonds are brought more effectively into play so that more of them have to be broken simultaneously." As soon as this new set of atomic bonds is stressed and

must be overcome it is to be expected that the rate of slip on the plane on which it is progressing will materially slow down. When this happens the amorphous metal will have its opportunity to cool down and to set.

Or again, if one wishes to reject the theory of Beilby as impossible (as Jeffries and Archer have done on page 703 of *CHEMICAL & METALLURGICAL ENGINEERING*, Oct. 12, 1921), he still may offer the following explanation to account for the stopping of slip on one plane and the beginning on another. Reasoning as before, the plane which has the fewest active atomic bonds will be the one upon which slip first occurs. After slipping to a slightly new position, a great many more atomic bonds may be brought into action. May not these new bonds, when brought into action, make this plane more resistant to further slip than it was in the beginning and more resistant than other planes upon which slip has not yet occurred? As slipping proceeds it may happen and perhaps does, that as stronger and stronger planes are slipped the one upon which slip first occurred may by the process of elimination again become the weakest plane. It therefore may slip again until an additional set of atomic bonds is brought into action. One plane, then, is not limited to slipping just once during rupture, but may slip a number of times depending on the atomic arrangement. O. A. KNIGHT,

School of Mines,
State College, Pa.

Associate Professor of Metallurgy.

Prof. Knight has made it clear that without some interference, slip once started should continue at a rate of speed determined by the frictional resistance of amorphous metal and the heat conductivity of the surroundings. Is it not reasonable to suppose that slip stops because the forces which started it are momentarily released?

Stresses in a test-piece are ordinarily distributed irregularly. But suppose uniform distribution across a test-piece of fine grained metal. Even then some crystals will be so oriented that the load will throw a shear of maximum intensity along the crystalline plane offering lowest resistance. As the loading increases, the shearing strength of this crystal is passed and slip starts. But any actual movement suddenly disarranges all the neighbors. The slip once started speedily becomes "jammed," the stresses once resisted by the yielding crystal are thrown into adjoining particles of metal which safely bear them. Immediately the outside forces are released, slip stops, and any amorphous material generated immediately freezes into a very rigid and strong substance.

It may be objected that a test-piece may be formed of a single crystal, and this crystal will show much ductility under load, finally breaking in a highly contracted area. There is no chance for transfer of load to neighboring crystals. But could not the release of stress be due to the fact that inertia of the testing machine or imposed load prevents the stress immediately following the very rapid movement of the broken crystal? If this is true, the load is released momentarily, movement stops, and the amorphous material generated at the slipping plane solidifies.

Immediately after this solidification there should be an added stress due to impact, when the load catches up with the lengthened specimen. A ductile material should withstand this impact; a brittle crystal, on the other hand, would fail. Perhaps this distinguishes between these qualities.

EDITOR.

Scientific Relief Suggested for Russian Chemists

To the Editor of Chemical & Metallurgical Engineering

SIR:—I read with great interest your editorial regarding the whereabouts of the famous Russian chemists and later your editorial on sending relief to them.

I have in hand the first issue of the Scientific-Technical Bulletin of the Supreme Council of National Economy, published by the Russian Government in Moscow in 1920. In this bulletin is given a review of many chemical publications, among which is one of Prof. Ipatieff's recent book, "A Course in Organic Chemistry," 416 pages, published in Petrograd in 1919. Furthermore, I have before me a recent Russian newspaper which gives the personnel and the work and achievements of the Russian Supreme Council of National Economy. This Council consists of eleven of Russia's foremost representative engineers and is the highest technical body engaged in working out the industrial program of Russia. Prof. Ipatieff is one of these eleven and the newspaper in question speaks very highly of his scientific contributions to the industrial reconstruction of Russia.

Your suggestion to send relief to the Russian chemists is indeed an excellent one and very practical. Perhaps the greatest contribution that American chemists and scientific men could at present make to stricken Russia is in the form of chemical and scientific literature, from which she has been shut off since the beginning of the great war.

May I suggest that you take the initiative and issue an appeal to American chemists and men of science, through the American Chemical Society, to send to Russia some scientific and chemical publications since the year 1914? No deed or act on the part of American chemists could be more noble or humanitarian than the execution of your suggestion. The Russians have expressed their appreciation and admiration for the American relief in the famine-stricken districts. Russia's scientific men will equally appreciate this scientific relief. History will, I have not the slightest doubt, prove this.

Such scientific contributions can be transmitted, for distribution among the higher institutions of learning, to the Scientific-Technical Department of the Commissariat for Education, Moscow; or it can be sent to the Society for Technical Aid to Russia, 110 West Fortieth St., New York City, for transmission to the above address in Russia.

I shall be glad to assist you in carrying out this plan. I have recently talked with Dr. Benjamin T. Brooks, who thought very highly of such relief to the Russian chemists.

JOSEPH R. MINEVITCH.

New York City.

EDITOR'S NOTE: We are glad to publish this letter emphasizing the importance of one phase of the relief program for Russian chemists outlined in an editorial in our Oct. 26 issue. The appeal should meet with a hearty response.

Correction

The title of the article by Wilbert J. Huff, published on page 865 of our issue for Nov. 9, 1921, was misstated. It should read "Corrosion Beneath Oil Films, and the Protective Action of Certain Colloidal Solutions."

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

LONDON, Nov. 15, 1921.

AS FORESHADOWED in my previous notes, the violent fluctuations and great depreciation in the value of German currency have influenced markets to a considerable extent and the general uncertainty has retarded recovery. On the other hand, quotations from abroad are now generally given in sterling and this method of compensating for fluctuations has slightly stiffened quotations, though as regards fine chemicals there is not much prospect of alteration in prices at present.

ON THE EVE OF IMPORTANT DEVELOPMENTS

It is notorious that new epoch-making British inventions have in the past been mainly developed abroad, but at the present time many new processes, to which a wealth of time and effort have been devoted, appear to be on the point of fruition. The barium process for the manufacture of cyanide is an example of close co-operation among the fuel expert, the expert on refractories and the highly trained chemical engineer. Calvert's process for the production of alcohol, referred to in my notes published on July 13, has now made further progress and it has been stated that with water gas at 15c. per thousand cubic feet, a production cost for power alcohol of 16c. per American gallon is in sight, while the capital outlay is relatively very low. It is understood that Calvert's process is now being tried out on an industrial scale and that important developments may be expected early next year. The idea of making alcohols from water gas is not new, but previous investigators appear never to have got further than the production of methane or ethylene, whereas Calvert obtains his product in one operation and of 50 per cent strength.

In this connection it is interesting to learn that Bury and Ollander's process for making alcohol from the ethylene in coke-oven gas is to be installed at two other plants, but it is considered to be unlikely that the cost of production will be less than 30c. per American gallon.

PROGRESS IN SYNTHETIC AMMONIA

The progress foreshadowed in my last notes regarding the Claude process has been realized and it is understood that the first installation will be in Norway and that work is to commence immediately. The electrolytic method of hydrogen manufacture will be used, under which the cost of production of hydrogen is expected to work out at 30c. per thousand cubic feet. The Claude catalyst tubes are to be made of Vickers special nickel-chromium steel, which appears to be very similar in all its properties to the new Krupp steel "V2A," which was used successfully during the war for a variety of chemical plant, including centrifugal pumps for nitric acid. Claude's tubes are 7 ft. long and 4 in. internal diameter and it is understood that the French Government Commission's report will pronounce in Claude's favor and against the Haber process. It was thought that the Oppau works would not be rebuilt until the success or failure of Claude's process was known, but it is now known that the works are to be restored with all speed and production is to be expected at the beginning of next year. The cause of the explosion can almost certainly be ascribed to the blasting

of mixed fertilizer, and it seems indefensible, however often the use of explosives had failed to detonate the fertilizer mixture, to have invited disaster by the use of such methods. The function of an explosive has always been to explode and with a potential explosive mixture of this kind, the risk was great.

BRITISH CHEMICAL ENGINEERS DISCUSS FORMATION OF AN INSTITUTION

The feeling that a qualifying body similar to the American Institute was necessary has been gathering momentum and culminated in a largely attended meeting just held at the Engineers' Club, at which it was decided to form a provisional institute and committee to inquire into the best method of organizing qualified chemical engineers. The provisional committee includes Sir Arthur Duckham, Mr. Woolcock, M.P., William McNab, Mr. Reavell and Prof. Hinchley, who has done practically all the spade work. It was mentioned at the meeting that the American Institute might decide, in accordance with a suggestion made recently, to call itself "The Institute of Chemical Engineers," and it seems quite probable and possible to arrange ultimately for an institution which shall embrace affiliated branches in all English speaking countries, rather than to form separate bodies. The possibility of utilizing the Institute of Chemistry as a qualifying body has been mooted in the past, but the present feeling undoubtedly leans toward the institution idea, the Institute of Chemistry having shown little sympathy with the movement. On the other hand, chemical engineering education is notoriously behindhand and until and unless degrees on chemical engineering are provided, the qualification for membership must rest mainly on achievement and distinction.

GENERAL PERSONAL NOTES

The *Times* Trade Supplement of Nov. 12 published a thoughtful article by Mr. Woolcock, M.P., general manager of the Association of British Chemical Manufacturers, in which the operation of the safeguarding of industries act is discussed in the light of the experience of the past two months. The attention of American readers may be drawn to the definitions of fine chemicals and the present position of synthetic camphor and milk sugar.

Something of a sensation was caused by the sudden reappearance of Dr. Paul Dvorkovitz, the well-known petroleum expert, who, after carrying out valuable work in the Allied interests in Russia, was definitely reported to have been shot by the Bolsheviks. One of the oldest members of the Society of Chemical Industry, Dr. Dvorkovitz received a warm welcome and entertained his many friends with details of his pleasant and unpleasant experiences in Russia.

Increased Duties on Competitive German Products

Acting Commercial Attaché S. H. Cross of Brussels reports that an emergency tariff act was put into effect Nov. 7 which covers exclusively German manufactured products entering into direct competition with Belgian industries. It provides for increases of 100 to 300 per cent on articles assessed by weight, and advances many ad valorem duties to 20 or 40 per cent.

Textile, chemical and mechanical products are prominent among the German products which are to bear increased duties.

The Aging of Rubber

Problems Arising in Studies of the Life of Rubber Goods—Methods of Testing—Aging Hypothesis—Additional Vulcanization by Oxygen—Depolymerization—Additional Vulcanization by Sulphur—Still and Active Aging Compared—Aging Under Strain

BY ANDREW H. KING

THE life of rubber goods is a subject of vital importance not only to rubber technologists but to the general public as well. The natural life of soft rubber goods seldom exceeds 30 years, but the average is much lower. For example, an average grade of garden hose seldom lasts more than 5 years, when it fails not from being worn out but because of certain changes which go on within the rubber compound. The cover will become checked or cracked and the tube and friction so stiff that the hose cracks open when bent. Similar conditions are found on some tires and occasionally on those of the best grades. Side-wall checking is usually the first warning of poor aging. One does not expect soft rubber goods to last forever, but just as in human life, there is a great divergence in mortality. There is a wide variation from brand to brand of the same article and not infrequently a variation just as wide in the product of the same manufacturer. In fact, there are cases where the article fails by bad aging before it is placed in service.

Bad aging can usually be traced to faulty materials or conditions of manufacture, but in many instances the conditions of service are responsible. In other cases the manufacturer has failed properly to appreciate the type of service desired and has produced an article designed for something else.

Naturally the blame for faulty aging from the manufacturer's standpoint falls on the rubber chemist. It is therefore not remarkable that at the last meeting of the Rubber Division of the American Chemical Society in New York the discussion on this subject was both extended and animated. It was characterized, however, by the wide divergence of opinions, ranging from the value of all artificial aging tests to the conditions deemed most suitable for performing them.

METHODS OF TESTING

The adequate determination of the life and service of any soft rubber compound requires at least 1 year's exposure; it is better that the exposure be for 2 or 3 years. Of course this method is entirely unsuitable for development work. One wishes to know approximately how his product will stand up in service and he wishes this knowledge as quickly as possible. This is the reason for the large number of artificial age tests which as a rule are merely each investigator's own method of attack on the problem.

The greatest single contribution to our knowledge on this subject has recently been published under the caption "Ten Years' Experience With Age Tests," by Dr. W. C. Geer and W. W. Evans of the B. F. Goodrich Co. (*India Rubber World*, September, 1921, p. 887). Their method in brief consists of heating test-pieces of the various compounds in an oven at 160 deg. F. (71 deg. C.) with a constant supply of fresh air previously

heated to the same temperature. Up to 4 or 5 days, 1 day's heating appears to give the same deterioration in tensile strength as is met with in 6 months of natural life. The test is comparative and therefore must always be run in conjunction with the same type of compound whose aging in natural life is known.

Their ideas on the subject may be summarized as follows:

1. It is more reliable to plot deterioration in tensile strength against time of heating and to determine the aging characteristics from the curve than to make simply one or two determinations at definite time intervals. In other words, it is the trend of data that determines.
2. Samples are not hardened as in actual aging, but are definitely weakened.
3. Sulphur changes are noticeable, but were not considered important.
4. The artificial age test is considered more severe than natural life.
5. The test is of little value for compounds having a tensile strength less than 1,000 lb. per sq.in.
6. The authors are of the opinion that in the majority of cases of too rapid deterioration, this is due to overcure or undercure and in the majority of cases to overvulcanization.

This paper was originally presented in England before the International Rubber Conference. The discussion that followed was quite interesting. Stevens stated he found that the moisture content of the air has a great effect on natural aging. Samples aged in moist air and immersed in water showed much lower deterioration than when exposed to heated air. Schidrowitz called attention to the absence of light in the test described above. DeVries stated that deterioration is more rapid in the tropics than in London. This may be due to more intense light. Dr. Geer in the course of further remarks mentioned that the current of heated fresh air in his test was very important and that it makes for uniformity of results. He also stated that fine para aged best, after which come the better grades of smoked sheets, which in turn are superior to pale crêpe.

OBSERVATIONS ON AGING TESTS

From the discussion of the aging question in New York the following observations are in order:

1. The majority of the chemists present perform their accelerated age tests at 70 deg. C. or thereabout.
2. Other investigators employ a comparatively high temperature—e.g., 130 to 150 deg. C. Their theory is evidently to treat the samples more severely than will be met with in service.
3. An interesting and highly practical test was described by Dr. Somerville. Test-pieces were placed in

ordinary Mason jars and immersed in boiling water for various periods of time. At the beginning of the test the samples are exposed to oxidation as well as to the action of heat. Within a short time the oxygen disappears and further deterioration is due to heat alone.

4. Sanderson described a new type of oven in which dry air previously heated to the required temperature is supplied continuously. The oven is immersed in a thermostat for the accurate control of temperatures.

An outstanding feature of the remarks was that very few had any concrete ideas or theories as to what aging actually is or how it progresses. Naturally this is considerable to expect on a subject so little understood. However, it is true that more satisfactory progress is always obtained when a moderately simple hypothesis is adopted as a means of visualizing the problem in the beginning.

AGING HYPOTHESIS

It is with precisely this object in mind that the following is presented. Let us assume for the present that the deterioration of rubber with age is solely dependent on additional vulcanization subsequent to the normal "cure."

By vulcanization we mean the addition of a substance or substances to rubber which results in the production of a more elastic material—i.e., one with less plasticity. When the change becomes of sufficient magnitude that the product becomes of commercial value it is then known as "cure." It is well known that substances other than sulphur or sulphur chloride—for example, oxygen, chlorine, selenium, etc.—produce a change in plasticity—in other words, that they vulcanize—but the products obtained this way have not to date had any commercial value and therefore cannot be called "cured." In speaking of additional vulcanization it is to be understood that we are not limiting ourselves to sulphur or sulphur chloride.

In vulcanization by sulphur there are two ranges within which the products have commercial value. The first or soft rubber range contains compounds vulcanized so that they have from 1.5 to perhaps 4 per cent combined sulphur on the rubber. When reclaims are used, this figure goes up to 6 or 8 per cent combined sulphur. Above this point there is a long intermediate range where the products are without value. Then we come to the range of the ebonites, which will run from about 20 to as high as 47 per cent combined sulphur on the rubber.

For purpose of argument we may assume that we can have vulcanization—for example by oxygen—in addition to the sulphur cure which preceded it. We may even assume that under proper conditions it is possible for oxygen or other vulcanizing substances to saturate the remaining free bonds of the rubber and produce a material related to $C_{10}H_{16}S_2$ (ebonite) or $C_{10}H_{16}Br_2$. Under the ordinary conditions of aging additional vulcanization by oxygen or by sulphur or by both are probably all that will be encountered.

Surface aging which results in a hardening and checking of the surface is probably due largely to additional vulcanization by oxygen. On the other hand, internal aging which lowers the tensile strength and the ultimate elongation is likely to be a combination of additional vulcanization by both sulphur and oxygen which may be released from the compounding ingredient or merely from the air dissolved in the stock during the milling. Such rubber has a perished smell and feel.

Additional vulcanization is probably affected by the following factors:

By Oxygen

- (a) Concentration and activity of oxygen.
- (b) Accelerators of oxidation such as
 - (1) Actinic light.
 - (2) Certain compounding ingredients—e.g., red lead.
 - (3) Impurities such as copper and manganese oxides or salts.
- (c) Depolymerization.

By Sulphur

- (a) State of cure.
- (b) Depolymerization.
- (c) Concentration and activity of sulphur.
- (d) Accelerators.
- (e) Heat.

Direct evidence of the combination of oxygen with rubber was found by Herbst (*Ber.*, 1906, vol. 39, pp. 523-525), who purified rubber by Harries' method—by dissolving in chloroform and precipitating with alcohol—which was repeated several times. The purified rubber he then dissolved in benzene, which cement was boiled under a reflux condenser; meanwhile passing dry washed air through the solution for 140 hours. On distilling off the benzene he found an increase in weight of 12.2 per cent. From the sirupy mixture of resinous bodies he was able to isolate two compounds having the empirical formulas $C_{10}H_{16}O$ and $C_{10}H_{16}O_3$. The latter he found to correspond in its properties to Spiller's resin.

An indirect evidence of vulcanization by oxygen is found in the scorching or lumping with change in elasticity, etc., sometimes noticed when large amounts of carbon black are milled into rubber without proper care in handling.

The action of ozone on rubber is well known. One molecule of O_3 adds on at each double bond. Ozone is extremely active. Obviously additional vulcanization by oxygen depends in a great measure on the concentration of oxygen present. In fact all protective coatings which retard or prevent surface aging do so by excluding oxygen.

ACCELERATION OF OXIDATION

Actinic Light.—Light is perhaps the most powerful catalyst of oxidation known. C. O. Weber (*J. Soc. Chem. Ind.*, 1903, p. 875) described experiments in which thin films of para, both crude and milled, vulcanized and unvulcanized, were exposed to light for 50 days. The acetone extracts of the samples were determined at intervals. His conclusions were:

1. That unvulcanized rubber was more liable to oxidation than vulcanized due to lower saturation state.
2. The longer rubber is milled on hot rolls the higher the acetone extract. With very excessive working the extract becomes gummy and not resinous, as is the case with truly oxidized rubber. Weber considered the increase in extract as due to the decomposition of the rubber molecule.
3. Overworked rubber oxidizes very rapidly, yielding after 50 days' exposure 38.7 per cent extract against 5.7 per cent when properly milled.
4. The lower the degree of vulcanization (probably referring to undercure) the faster the oxidation.

Additional evidence is furnished by Gorter (*Gummi Zeit.*, vol. 30, p. 351, 1916), who exposed samples of rubber to light in sealed tubes containing air, oxygen, carbon dioxide and hydrogen. The rubber became tacky only in those tubes containing air or oxygen. Oxidation proceeded slowly during the first 6 days, then more rapidly, reaching a maximum in about 30 days.

The presence of aldehydes in the tacky rubber was established.

Since light has the property of accelerating oxidation, it is to be expected that increased oxidation would result with an increase in the ultraviolet. That this is so was shown by Henri (*Le Caout. et Gutt. Percha*, 1910, vol. 7, pp. 4371-4376), who exposed sheets of fine para, pale crêpe, hevea latex evaporated on glass, rubber cement evaporated on glass and sheets containing various minerals to the action of light rich in ultraviolet, secured from a mercury vapor lamp placed 20 cm. from the samples. He found:

1. Unvulcanized rubber suffers visible deterioration in 20 hours. It darkens and becomes shiny. The surface cracks when sample is stretched.
2. Action is superficial only, with brown cut sheets.
3. But with pale sheets it penetrates quickly.
4. Vulcanized rubber requires 48 to 72 hours' exposure for deterioration to become noticeable.
5. Minerals slow down the action in some cases. Thus litharge tends to restrict and antimony pentasulphide to increase the oxidation.
6. Rubber from solution in naphtha is more easily attacked than the undissolved.
7. He concluded that the change is due to oxidation, which is accelerated by ultraviolet rays.
8. The most active rays have a wave length of less than 3,600 Angstrom units and are not screened off by thin sheets of glass. Absorption of oxygen by a very pale sample was found to begin at a wave length of 3,650 units. As rubber darkens in color the absorption of ultraviolet rays increases.
9. Due to the fact that ultraviolet concentration is greater with higher altitudes, balloon fabrics should be coated with an ultraviolet screen containing pigments such as lead chromate or aniline yellow.

Certain Compounding Ingredients.—Red lead (Pb_3O_4) was at one time rather extensively employed. However, it was found that most stocks containing it failed from internal aging.

An example of oxygen vulcanization is found in Ostromuiski's mono- and di-nitrobenzene processes, in which litharge plays the part of a catalyst of oxidation. The oxygen comes from the di- or mono-nitrobenzene, the reduction products of which may be determined in the vulcanized compound.

Impurities.—Copper and manganese compounds and probably alkali are other catalysts of oxidation which are occasionally found as impurities in various compounding ingredients. Apparently not all compounds of manganese have this effect, for a certain zinc oxide which gives compounds of excellent life contains traces of manganese.

DEPOLYMERIZATION

The conception most generally held is that the colloid rubber is made up of colloidal aggregates of unknown but possibly varying size. These aggregates probably consist of a large number of $C_{10}H_{16}$ molecules linked up through the partial valences of the double bonds, of which there are two to each molecule. We may write rubber as $(C_{10}H_{16})_n$, where n represents the number of molecules in the aggregate.

The tying up of the rubber molecules into the colloidal aggregates renders them less reactive due to local saturation of the partial valences. A somewhat analogous case is found in the benzene ring, which contains three double bonds yet does not react very readily

until something happens to break in some way the local or self-saturation of the partial valences of these bonds.

By depolymerization we mean the splitting up of the aggregates into others of smaller size. In ordinary milling the "breaking down" or plasticizing of the rubber probably corresponds to a reduction in size proportional to a change from n of 3,000 to one of 2,500. There is doubtless some relation between increase in plasticity and decrease in size of the aggregate. Within small limits there is the property of partial recovery. Thus milled stocks harden on standing. The change is probably proportional to an increase of n to 2,800. Partial recovery decreases with the severity of treatment. There is evidently a limit below which rubber remains permanently soft and tacky.

Polymerization is without doubt the greatest unsolved mystery of rubber chemistry. We know how to reduce it, but no one to date has shown how it may be increased without introducing some material as for example sulphur, which polymerizes by tying up the loose ends, or as may be better described, the locking of one molecule to another through their double bonds. Unfortunately sulphur when once in place so far has refused all invitations to let go its grip.

FACTORS AFFECTING DEPOLYMERIZATION

The factors affecting depolymerization are temperature, time and solvents. It appears to be nothing more than a physical separation of the aggregates into smaller units. It ought therefore to be proportional to the time and temperature of heating. The higher the temperature or the longer the period of heating the greater should be the depolymerization.

In normal vulcanization by sulphur we have two reactions, that of heat, which produces depolymerization, and that of sulphur, which increases the polymerization as described above. Naturally the shorter the time or the lower the temperature the less the depolymerization and therefore the less sulphur required to combine with the rubber to produce a normally cured product.

The depolymerizing properties of certain solvents are probably due to similar causes. Perhaps the most likely theory is that the rubber absorbs the solvent and swells in much the same manner as gelatine swells when immersed in water. The volume of the gel increases, but the total volume of gel plus water decreases—i.e., the process is accompanied by compression. The force exerted is terrific and probably runs into the hundreds of atmospheres. There is an evolution of heat, which in the case of gelatine amounts to 5.7 gram-calories per gram of gel. Swelling of rubber in solvent brings about a separation or dissociation of the molecules in the aggregates.

As pointed out above, depolymerization is a separate and distinct reaction from vulcanization. No matter how carefully vulcanized a product may be, if it is exposed to excessive heat or to certain solvents it will become depolymerized. This within small limits is probably harmless. Its bad effect, however, is that it opens up double bonds and makes them available for addition. This will take place with sulphur if there is sulphur and a sulphur catalyst available. If not, oxidation will begin. It is for this reason that most compounders try always to have a small residuum of free sulphur in their compounds.

It will be noticed in the experiments described under the effect of light and also under accelerated age tests that the samples became soft, tacky or weakened. Ap-

parently in these cases the rate of depolymerization exceeded that of addition of oxygen. In natural life tests perished rubber is most always hard and practically brittle. It has a characteristic odor. It is reasonable to suppose that the difference is due merely to the period of exposure and that, given time enough, the soft, tacky samples would also have become hard.

ADDITIONAL VULCANIZATION BY SULPHUR

State of Cure.—Additional vulcanization by sulphur is the principal factor in internal aging. Dr. Geer's statement that the cause of most bad aging is due to an overcure or an undercure and usually to an overcure is only too true. The uninitiated sometimes prefer a stock cured so that it has a great deal of snap. This is wrong, because the point of maximum snap lies on the overcured side. The correlated opinion of men who have been a long time in the business is that the best cure from an aging standpoint is a little short of that cure giving maximum tensile strength. The cure giving from 10 to 15 per cent less tensile than the maximum is usually preferred.

A study of the bloom is also helpful. This term is given to the deposit of sulphur which condenses on the surface after the cure to a more or less extent, depending on the amount of free sulphur remaining in the stock. It is usually desirable to examine stocks for bloom about 6 weeks subsequent to vulcanization. Many experienced compounders can pick out the best cure of a stock by simple appearance of sheets cured at different times, after the bloom has had an opportunity to develop. In very few cases will the non-blooming stocks be chosen, because in many instances they will be found to be overcured. Nor will those having a pronounced bloom be selected, for the reason that their cure is probably under. In most cases the optimum cure will be taken as the one where a slight but not excessive bloom is in evidence. In compounds becoming non-blooming in about 2 hours and 30 minutes curing time at 141 deg. C., this point will be found about 15 minutes previous to the non-blooming cure.

The best types of antimony tubes are practically but not quite non-blooming. But antimony sulphide is a special compounding ingredient. It appears to act as a stabilizer. For example, the theory is that as the tube becomes depolymerized because of the heat and flexing, the pentasulphide decomposes slowly and the liberated sulphur adds on to the rubber, thus neutralizing the effect of depolymerization. This theory has been advanced as a solution of the problem why antimony tubes maintain about the same physical properties over a long period of time. Some tubes are known to have been in service for more than 10 years without any serious deterioration. There are other substances which are even better stabilizers than antimony sulphide, as for example certain organic accelerators.

Many rules have been given for the proper free sulphur content. In many if not in all cases they are positively worthless, because free sulphur content is not nearly the whole story. The nature and amount of accelerator remaining after the cure are of equal if not paramount importance. Nor is the coefficient of vulcanization in itself a reliable criterion. This coefficient—the name given by C. O. Weber to the per cent combined sulphur based on the rubber—is very low. A good commercial cure may be obtained with a coefficient of but 1.5. On the other hand, such a compound will be badly overcured when a coefficient of 2.5 is reached.

In Weber's day this value was the minimum coefficient with which a commercial product could be obtained.

Depolymerization.—This subject has been discussed at some length above. Practically all the remarks apply to addition of sulphur as well as of oxygen. Perhaps the only difference is that with sulphur alone there is a temperature coefficient that prevents the addition of sulphur until a definite temperature is reached. On the other hand, there are so many powerful accelerators which work well at low temperatures that in most cases depolymerization is a decided factor in internal aging. This is particularly the case for those compounds containing substances known to be violent depolymerizers such as certain grades of rosin oil.

Concentration of Sulphur. Accelerators.—These subjects are so interwoven that it is almost hopeless to separate them. For a time the tendency was to make practically non-blooming stocks by the aid of powerful organic accelerators. Older compounders have always insisted on a liberal supply of bloom. Today it is believed that an intermediate position is most desirable. The proper accelerator and sulphur ratios can be determined only by long experience. A compound should stand 100 to 200 per cent overcure without serious deterioration in physical properties.

Heat.—As is well known, heat speeds the reaction of sulphur with rubber during the cure. It also has a similar effect in speeding after vulcanization, but to a much less extent than at the normal curing temperatures. From an aging standpoint its worst effect is as a depolymerizer.

COMPARISON BETWEEN STILL AND ACTIVE AGING

A peculiar and apparently inexplicable phenomenon is the fact that rubber resists age better when in use than when idle. It is well known that a spare tire ages badly in comparison to its sister on the wheel in service.

Just why this is so is not yet known. The temperature of the exhaust is perhaps a small factor. But a more likely theory is that some internal rearrangement has taken place within the rubber itself. The stresses of a tire in service are greatly different from one held in reserve as a spare. In the latter case the entire carcass is under strain from the inside. This permits the tire to take a set along certain lines. When put in service the stresses are from an opposite direction and failure soon occurs. The exact cause of the trouble, as mentioned above, is not known. In the meantime it will be found desirable to keep spares covered and to put them in service at least every 3 months.

It has been observed that many otherwise good aging compounds when placed under strain, even so slight as when an 8-in. sheet is bent double, and exposed to the weather soon develop serious cracks and checks at the location of greatest tension—i.e., on the outside of the bend. Just why this is so is not yet known.

CONCLUSION

Several ideas as to the cause and mechanism of aging have been correlated. The hypotheses advanced are not considered as proved, but are merely tenable in the light of present knowledge.

There is no more serious problem facing rubber manufacturers and consumers today than the study of aging. It may be said without fear of contradiction that the average life of soft rubber goods as prepared at present could be greatly increased without much effort.

On the Heat-Treatment of Aluminum Bronze

Exceptionally High Values Given in Handbooks for Strength of This Alloy Led to an Extensive Investigation of the Alloy for Use in Lifting Jacks—Hardness and Strength of These Bronzes Appear to Be Independent Variables

By A. A. BLUE
Metallurgist

MUCH valuable work has been done and published on the heat-treatment, with its attendant changes in structure and physical properties, of what is known as "aluminum bronze," an alloy of the general analysis: copper, 90 per cent; aluminum, 10 per cent, with occasionally 1 per cent iron substituted for a corresponding amount of copper. Under the necessity of producing lifting jacks of ever-increasing capacity with decreased weight, this alloy has been experimented with in various structural conditions. Since the large majority of the available data on this subject is made up from laboratory work done on small pieces, especially prepared, the results of the present investigation are offered, not with the idea of presenting considerations essentially new, but in the hope they may be of value to those who are interested primarily in the commercial application of this interesting material and in the results they may expect to obtain under actual conditions of everyday manufacture and treatment. Reference to the literature on heat-treatment of aluminum bronze reveals differences in opinion as to the nature of the changes involved and also as to the results obtainable from various treatments. After being unable to check some published results of treatments when applied in practice, a rather complete investigation was determined upon.

Cu:Al EQUILIBRIUM DIAGRAM

The theoretical considerations are embodied in the constitutional diagram shown in Fig. 1, taken, with a slight modification, from Greenwood¹. This arrangement was in turn prepared from the work of Curry², Carpenter and Edwards³, and Andrew⁴. The constitution of the alloys of copper and approximately 10 per cent aluminum consists of a series of solid solutions, the nature and designation of which have not been entirely agreed upon, but, as Fig. 1 is made up of what has been considered best in a number of the most carefully conducted works on the subject, it is probably very close to correct.

Alpha solid solution exists alone up to approximately 10 per cent aluminum, under conditions of equilibrium. An inclination in the boundary line exists above 1,050 deg. F. (566 deg. C.), thus permitting the appearance of the second phase, known as beta solid solution at higher temperatures. Curry² and Rosenhain⁵ show this boundary line at approximately 8.5 per cent Al,

but the work of Greenwood demonstrated the difficulty of obtaining the alloy in equilibrium, which accounts for the different locations of this line. The present work has been done with samples containing varying amounts of iron, which has also probably shifted the equilibrium. Increasing aluminum beyond 10 per cent produces a third solid solution known as delta, which forms a eutectic with alpha, the eutectic composition being approximately 12 per cent aluminum, as indicated in Fig. 1. Upon heating past the transformation temperature (1,050 deg. F., 566 deg. C.), the eutectic changes into the beta solution, which proceeds

FIG. 1. PORTION OF THE Cu:Al
EQUILIBRIUM DIAGRAM,
AFTER GREENWOOD¹

to absorb increasing amounts of alpha or delta, whichever was the excess constituent, with increasing temperatures, as shown by the lines *CK* and *KE*. At 1,400 deg. F. (760 deg. C.) indicated by the line *HI*, the delta solution changes into a fourth form known as gamma. The melting point of the alloy is seen to be in the neighborhood of 1,900 deg. F. (1,040 deg. C.) along the line *ABCDEG*.

MICROSCOPIC APPEARANCE OF CONSTITUENTS

The structural appearance of bronzes containing varying amounts of aluminum on both sides of the value represented by J is shown in Figs. 2 to 5 inclusive. Fig. 2 is of a sample containing 7.54 per cent Al; practically all of one constituent, with here and there a slight appearance of the eutectic. The round black spots are of lead, which is insoluble in copper. A somewhat larger amount of eutectic is visible with 8.39 per cent Al, though it may be largely

Fig. 2. 7.54 per cent Al

Fig. 3. 9.48 per cent Al

Fig. 4. 0.76 per cent Fe

Fig. 5. 1.23 per cent Fe

masked by contrasty etching. Fig. 3 shows bronze containing 9.48 per cent Al; 10.4 per cent gives progressively increasing amounts of the black eutectic constituent. All of these samples contained approximately 0.5 per cent iron. Increasing the amount of iron appears to cause a bunching of the crystals around the large grain boundaries, as shown in Figs. 4 and 5, containing respectively 0.76 and 1.23 per cent iron.

All micrographs are after etching with FeCl_3 , acidified with HCl .

The effect of heating the same samples is shown in Figs. 6 to 8 inclusive, all samples being heated to 1,600 deg. F. (870 deg. C.) and quenched in a 5 per cent brine solution. The eutectic is seen to have changed into the fine needle-like beta solution, which has in turn absorbed some of the adjacent alpha, so that the area of the beta is in all cases greater than that of the eutectic from which it was produced. Fig. 8 is practically complete beta solution. Along the grain boundaries a small amount of alpha reappears no doubt due to the quenching not being sufficiently rapid.

The results obtained from various rates of cooling are illustrated in Figs. 9, 10 and 11, showing, respectively, the structures resulting from quenching samples of the same composition from 1,550 deg. F. (845 deg. C.) in oil, water and salt water. The effect of annealing is to produce a very much refined structure, as shown in Figs. 12, 13 and 14 of samples heated to 1,550 deg. F. (845 deg. C.), cooled in air; 1,600 deg. F. (870 deg. C.), cooled in lime, and 1,700 deg. F. (925 deg. C.), cooled in lime, respectively.

As indicated by the inclined line *BJ* in Fig. 1, increased temperatures above 1,050 deg. F. (566 deg. C.) produce increased amounts of beta solution, which is retained upon quenching. The actual progression of this absorption is shown in the series Figs. 15 to 20, inclusive, of samples heated respectively to 1,250, 1,300,

1,400, 1,500, 1,600 and 1,700 deg. F., in each case being quenched in 5 per cent brine. Progressive disappearance of the alpha solution is seen up to the temperature of 1,600 deg. F. (870 deg. C.), when complete solution is found. Further heating above this point appears to develop a formation along the grain boundaries. Greenwood states that this is a reappearance of alpha. It is apparent, as noted above, that some alpha is to be expected due to the impossibility of retaining all in solution during quenching, just as it is practically impossible to obtain pure austenite in quenching carbon steels, but it appears difficult to justify a larger amount of alpha at higher temperatures than at lower ones, when just the reverse is to be expected. It

TABLE I. ANALYSES OF SAMPLES USED

Mark	Copper	Aluminum	Iron	Lead	Tin	Brinell Hardness (500 Kg.)
1	89.09	7.54	0.61	1.05	1.32	57
2	90.66	8.39	0.29			70
3	90.82	8.75	0.33			70
4	90.09	9.42	0.50			100
5	89.56	9.45	0.67			100
6	89.66	9.48	0.54			100
7	89.31	9.61	1.23			93
8	89.05	9.73	0.57			100
9	89.70	9.90	0.37			100
10	89.05	10.06	0.76			119
11	89.12	10.13	0.45			119
12	88.54	10.39	1.26			93

appears more reasonable to assume that this formation is due to a coagulation of the beta crystals themselves, with probably less alpha present than before. A number of specimens examined after such treatment showed a marked increase in this formation along the grain boundaries with the higher temperatures, so that the phenomenon is not accidental.

EXPERIMENTAL PROCEDURE IN QUENCHING

As noted above, samples of various analyses have been employed in the present discussion, coming from two foundries, one being an ordinary brass and bronze foundry and the other possessing an organization which has specialized on this alloy for a number of years. The analyses of the various samples used, together with the initial Brinell hardness figures, are shown in Table I. Greenwood found that samples 0.4 in. thick or larger

could be used without affecting the scleroscope values obtained. Accordingly, a number of samples from $\frac{1}{2}$ to $\frac{3}{4}$ in. square were made up from castings of the above analyses. These samples were mixed indiscriminately, heated to various temperatures, and cooled at various rates, two samples being run for each condition. The samples were heated in an electric muffle, ample time being allowed for the metal to soak at the desired temperature; they were then rapidly removed to the proper cooling medium. If liquids (at room temperature) were the coolant, the piece was kept in constant motion during the cooling period. Temperatures were accurately controlled by a Leeds & Northrup poten-

FIGS 12, 13 AND 14. EFFECT OF ANNEALING BRONZE CONTAINING 10.13 PER CENT AL. $\times 25$

Fig. 12. Cooled in air from 1,550 deg. F.

tiometer, the couple being in actual contact with the material in the furnace. The results of these tests, showing Brinell and scleroscope values before and after treatment, are shown in Table II. The magnifier hammer was used in all cases with the scleroscope, and the 500-kg. weight for the Brinell, except as noted when a corresponding correction was made, according to Fig. 21.

The results of the above series are plotted, Fig. 22 showing the increase in Brinell hardness and Fig. 23 in scleroscope. Due to the varying degree of hardness of the initial pieces, as a result of the increasing percentages of aluminum, the *percentage increase* in each case has been used, instead of the actual figures, as it was thought this would give a more accurate indication of the effects of the various conditions of treatment. Inasmuch as the samples lowest in aluminum showed no increase in hardness from treatments, these have been disregarded in plotting the curves. An examination of these curves shows a maximum harden-

FIGS. 15 TO 20. ABSORPTION OF ALPHA SOLUTION ON PROGRESSIVELY HIGHER QUENCHING. BRONZE CONTAINING 10.06 PER CENT AL. $\times 25$

ing effect at from 1,550 to 1,600 deg. F. (860 deg. C.) for all rapid coolings; 5 per cent brine, water and oil producing hardening effects in that order.

Annealing produces a slight softening of the bronze with apparently little to choose between air and lime cooling.

A close examination of the plotted points shows a drop in the Brinell hardness when quenched from 1,400 deg. F. (760 deg. C.) in oil, water or brine. Seidell and Horvitz⁸ show a similar drop, using straight aluminum bronze with no iron, at about 1,100 to 1,200 deg. F. (620 deg. C.) Greenwood's experiments showed that heating at 1,100 deg. F. (600 deg. C.) for 20 days was necessary to arrive at complete equilibrium. Heating to about 1,300 deg. F. (700 deg. C.) apparently permits this equalization to proceed more rapidly, resulting in the softening effect just mentioned.

A second series of tests was next made from the

same lot of samples, all pieces being quenched at 1,600 deg. F. (870 deg. C.), in brine, and drawn at various temperatures, with various rates of cooling after the draw. The results of these experiments showed a progressive softening of the material as the drawing temperature was increased with no marked or consistent difference appearing with various cooling media. The data are included in Table II.

As noted above, the material used in the tests just

FIG. 21. RELATION BETWEEN BRINELL HARDNESS OF ALUMINUM BRONZES AS DETERMINED BY 500 KG. OR 3,000 KG. LOADS

described was obtained from two sources, one being an ordinary brass foundry and the other an organization which has specialized upon this material. As the samples from the latter were found to be more uniform in composition and to contain fewer casting defects, several bars for further tests were obtained from this source. The analysis of these bars was Cu, 88.54 per cent; Al, 10.39 per cent; Fe, 1.26 per cent.

These bars were cast 1 in. diameter by 10 in. long,

and were quenched at varying rates from two temperatures, 1,600 deg. and 1,780 deg. F. (870 and 970 deg. C.) respectively; then drawn back to various temperatures, again with different rates of cooling after the draw. The bars were then cut into test bars as follows:

Tensile Tests. The central portion was turned down to the standard 0.505 in. diameter, allowing 2 in. for the determination of elongation.

Compression Tests. Test-pieces $\frac{1}{2}$ in. long by $\frac{1}{2}$ in. diameter were prepared.

FIG. 23. CHANGE IN SCLEROSCOPE HARDNESS OF ALUMINUM BRONZES AFTER COOLING AT DIFFERENT RATES

Impact Tests. Charpy test-pieces were prepared, 10 mm. square with a standard notch, $1\frac{1}{2}$ mm. wide by 5 mm. deep.

All test-pieces were very carefully machined, being held accurately to the dimensions given, plus or minus 0.0005 in. Brinell tests were also made on these bars, using 3,000 kg. in all cases except the untreated bar. The results are plotted in Fig. 24. It is seen that a draw to 700 deg. F. (370 deg. C.) renders the material

FIG. 24. EFFECT OF DRAWING ALUMINUM BRONZES AFTER QUENCHING IN WATER FROM 1,600 DEG. F.

harder than it was after the quench alone. A similar result is reported by Corse and Comstock¹ and by Portevin and Arnon², although Seidell and Horvitz³ found no such effect.

POOR CORRELATION OF PHYSICAL PROPERTIES

The tensile results, together with the other values obtained from this series of tests, are shown in Table IV. These figures present rather surprising results. In the first place, the large number of piped and defective pieces coming from a manufacturer with much experience indicates most forcibly the difficulty of handling this material in the foundry. However, the absence of all relation between Brinell hardness and tensile properties and between tensile properties and treatment is indeed unexpected. One feature especially peculiar (and apparently consistent) is the inverse ratio found between tensile strength and yield point. While the Brinell and scleroscope values respond very readily to treatment, they do not indicate any corresponding tensile strength and yield point, as they do with steel.

The above tensile tests were made on bars which had simply been turned down in the center. It was felt that possibly the low results were due to inequalities in the pull exerted by the testing machine. Therefore a number of threaded-end test-bars were prepared from addi-

FIG. 25. TRANSGRANULAR FRACTURE IN ALUMINUM BRONZE. $\times 100$

tional bars, cast with especial care to avoid all foundry defects. These bars showed an improvement in the condition of the metal after heat-treatment, as shown by figures for elongation and reduction in area, but the tensile strength and yield point were practically unaffected. Typical results were as follows:

Heat to 1,700 deg. F., quench in brine; draw at 1,000 deg. F., cool in lime.

Brinell hardness 179 (3,000 kg.).

Tensile strength, 81,495 lb. per sq.in.; yield point, 32,500 lb. per sq.in.; elongation, 22.5 per cent; reduction in area, 23.7 per cent.

Tensile strength, 79,480 lb. per sq.in.; yield point, 20,000 lb. per sq.in.; elongation, 20 per cent; reduction in area, 22 per cent.

Such results do not warrant discarding the first results obtained with the plain end test-bars.

Compression and impact results listed in Table IV indicate a draw at approximately 1,100 deg. F. (595 deg. C.) to give the best results. The increased brittleness shown by the impact test with a draw at 900 deg. F. (480 deg. C.) is very marked. This is of the same nature as the increased Brinell hardness with low draws, shown in Fig. 24.

Results obtained from castings made for lifting jacks substantiated the above results. The castings in question carry the entire load on the jack, delivering the load to a screw turning in the bronze casting. These castings were treated under all reasonable quenching temperatures, drawing temperatures and cooling rates from both heats. Brinell hardness figures corresponding to those given above for the test-bars were consistently obtained on the castings, but they all failed in service tests at approximately the same load, untreated doing as well as treated.

FRACTURE IS TRANSCRYSTALLINE

The failure of treated castings demonstrated a point of interest and one in accord with theory. Examination of fractures, as shown in Fig. 25, show the break to pass through the grains and not along the boundaries. This is as would be expected from theoretical considerations, inasmuch as the hard brittle beta is in the interior of the grain, while the softer more ductile alpha solu-

tion commences its formation along the grain boundaries, thus increasing the toughness at these points.

One of the prominent engineering handbooks on the market gives 100,000 lb. per sq.in. tensile strength to be expected from *forged* aluminum bronze. Actually to test this, bars 1 in. in diameter were forged at a temperature of 1,600 to 1,700 deg. F. to $\frac{3}{4}$ in. in diameter, treated as indicated in Table V, and turned to standard 0.505-in. threaded-end test-bars. The forged structure had a marked grain refinement, and the results

TABLE V. PROPERTIES OF FORGED ALUMINUM BRONZE

Treatment	Tensile Strength, Lb. per Sq.In.	Elastic Limit, Lb. per Sq.In.	Elongation, per Cent	Contraction in Area, per Cent

Drawn to 1,000 deg. F., cooled in brine	86,490	47,760	12.0	14.9

show some improvement in tensile properties, but an increase in brittleness in the heat-treated specimens; compare cast and forged bars, quenched and drawn to 1,000 deg. F. (540 deg. C.) cooled in lime. A small increase in tensile strength is accompanied by a 40 per cent drop in elongation. Likewise the bar quenched and not drawn shows a considerable increase in strength, but was so brittle that it broke at the end, even though threaded-end test-bars were used and generous fillets provided.

The fact that mechanical working of the bronze produces little effect upon its tensile properties is brought out by Corse¹⁰; he states that rolling has been found to be of little value in this regard, describing the circumstance as a "remarkable metallurgical fact."

CONCLUSION

In conclusion it may be said that: (1) The theory of the copper-rich aluminum alloys is apparently well developed. (2) Heat-treatment produces marked and consistent changes in Brinell and scleroscope hardness. (3) Heat-treatment produces little or no effect on tensile strength and yield point. (4) Forging produces little effect on the tensile properties of the alloys. (5) Aluminum bronze is very difficult to handle in the foundry and at present yields uncertain results. (6) Figures have been published on the value of this alloy which cannot be readily duplicated in actual practice or tests.

World Reserves of Water Power

The Siemens Schuckert Co. has compiled data on the world reserves of water power. The following are some of the figures, condensed:

Of the estimated total 745 million hp.

65 millions are in Europe.

160 millions are in North America.

94 millions are in South America.

236 millions are in Asia.

160 millions are in Africa

30 millions are in Australia.

Compared to population South America leads with 5.25 hp. per inhabitant, followed by Australia, with 3.75 hp.; North America, 1.27 hp.; Africa, 1.14 hp.; Asia, 0.27 hp., and Europe, 0.13 hp. per inhabitant.

Importance of the Olefine Gases and Their Derivatives

IV—Isopropanol (Isopropyl Alcohol)*

Commercial Preparation of Isopropanol From Propylene—Properties Depend to Some Extent Upon Method of Manufacture—Non-Potable Character Makes It an Important Industrial Alcohol—No Serious Physiological Effects—Interesting Possibilities for Use in Chemical Synthesis

By GEORGE O. CURME, JR., AND E. W. REID

IT IS interesting to note that within the past twelve months still another of the lower aliphatic alcohols has been removed from the list of materials available for pure science only and has taken its place among the commercial products open for development to our chemical industries. This alcohol is that one commonly known to chemists as isopropyl alcohol, but which will be termed isopropanol by the writers, as a more suitable common name.¹ The commercial introduction of isopropanol was first announced in this country late in 1920 by Ellis² as a product derived from the waste hydrocarbon gases of the Burton refining process. According to trade reports, it was also introduced industrially in Germany at about the same time. Further, the writers' company has been producing it on a commercial scale since early in the present year. As in all of these cases this product is being derived from gaseous propylene, and, moreover, is still relatively unknown to many industrialists, it finds a place among the other products of the new olefine gas industry which deserve to be better known by the chemical public.

The first description of isopropanol was given by Berthelot³ in 1855, who prepared it by the absorption of propylene in sulphuric acid and the subsequent hydrolysis of the reaction product in water. Judging from his analyses, Berthelot was at first led to believe that this product was the *n*-propyl alcohol, and reported his discovery as such. At a later date Friedel⁴ prepared this same product from acetone by reduction with sodium amalgam, and noted the identity of his product with that which Berthelot had prepared. It was not until the work of Kolbe,⁵ however, that the identity of this material was cleared up and isopropanol was shown to be the first member of the series of secondary alcohols. Still another source of isopropanol has been reported—

namely, the fusel oil from the abnormal fermentation of grain,⁶ in which it is said to occur to a limited extent. This source has been a matter of dispute and is of little importance from a production standpoint. A limited amount of isopropanol has always been available for scientific purposes, and this was made almost exclusively by the process of reduction of acetone with sodium⁷ or with hydrogen.⁸ Naturally from this latter source it would be impossible to prepare the material cheaply by any process, since acetone itself has always been much more expensive than commercial alcohol. Accordingly, until the technical development of the cheaper propylene process was accomplished, isopropanol could not sustain itself in competition with the other alcohols.

PROPERTIES

The pure product, (C₃H₇OH) is a colorless liquid with a pleasant alcoholic odor. It boils at 82.44 deg. C.⁹ at 760 mm. and has¹⁰ a density $D_{15}^{15} = 0.7903$. As is characteristic of the lower aliphatic alcohols above methanol, it forms a constant boiling mixture with water. It is in this form that it is being produced chiefly and may expect to have the widest application, just as is the case with grain alcohol. This constant boiling mixture contains 90.1 per cent isopropanol by volume or 87.9 per cent⁹ by weight. It boils at 80.37 deg. C.⁹ and has a density $D_4 = 0.8336$.⁹ An excellent table of specific gravities of isopropanol:water mixtures has been prepared by Lebo.¹¹ Some of the commercial grades, when prepared from gaseous mixtures containing olefines other than propylene, may contain certain amounts of ethyl alcohol—from ethylene—and also of secondary butyl alcohol—from butylene. This latter impurity is objectionable in some uses in that it gives a strong odor to the resulting product. Furthermore, there is the possibility of commercial grades being contaminated with an insoluble oil, a polymerized product of propylene, if not properly rectified in the production process. This also gives a distinctive odor to the material and is recognized by the turbidity given on dilution with water.

In the process of manufacture described by Ellis,¹² the gaseous mixture, containing propylene along with other ethylene and other olefine vapors, is first treated with sulphuric acid under conditions that absorb the higher olefine material, permitting the propylene and

A contribution from the Mellon Institute of Industrial Research of the University of Pittsburgh.

*This article, the fourth of a series of five, treats of the most recent addition to the family of available industrial alcohols. It is now being produced in the development work carried out by the Carbide & Carbon Chemicals Corporation. Parts I, II and III were published Nov. 16, p. 907, Nov. 23, p. 957, and Nov. 30, p. 999, respectively.

¹For commercial reasons it seems preferable to avoid the use of the word "alcohol" in designating a non-beverage material, as has been agreed by manufacturers and users of methanol and butanol. Accordingly, the writers propose the descriptive name isopropanol as a suitable designation for this new industrial product. The trade-name "petrohol" has already been adopted by the Standard Oil Co. of New Jersey for the commercial isopropanol which it has already placed upon the market. Since many other alcohols can equally well be made from petroleum and since isopropanol was first made from another source, this name does not seem well adapted for general use. Our industrial nomenclature will be much simplified to avoid such ambiguous terms, and to hold to names with a sounder chemical derivation.

¹²Ellis, *loc. cit.*

ethylene to pass unabsorbed. By a second treatment the propylene only is absorbed in strong sulphuric acid and a solution of isopropyl sulphates in sulphuric acid is thus built up. By a subsequent hydrolysis of the reaction mixture with water, the sulphates are changed to the alcohol and the pure isopropanol is rectified to the constant boiling mixture. In the process in use by the writers certain of the above steps are avoided. From the sources mentioned in an earlier paper,¹³ a gas containing none of the olefines but propylene is used for absorption in sulphuric acid, by a procedure that yields pure isopropanol directly on hydrolysis.

NON-POTABILITY AN IMPORTANT PROPERTY

In its general physical and solvent properties, isopropanol stands much closer to ethyl alcohol than does any other of the aliphatic alcohols, and consequently its applications may be expected to be in the nature of amplifying the supply of industrial alcohol available. It does possess the one great advantage that it is not a potable alcohol. Since this is true, it can be used in the pure form without need for any added denaturant, which is a material advantage in many applications. Indeed in most applications of isopropanol as a solvent or for other purely physical purposes it is so close to denatured alcohol in its properties that it may well be considered as a naturally denatured alcohol requiring no tax, no legal restrictions and no supervision.

By action of the Commissioner of Internal Revenue on June 15, 1921, isopropanol became a permissible substitute for acetone in the denaturing formulas 39, 39-A and 40. This is an official recognition of its non-potable character and at once offers a very considerable outlet for this new product in the production of denatured alcohol for uses where the strong odor of other denaturants is objectionable, such as in perfume manufacture, lotions for external application, etc.

PHYSIOLOGICAL EFFECTS

In the use of isopropanol there is not the poisonous effect noticeable that is so characteristic of methanol. It may be handled quite safely without any but the most common precautions against inhaling high concentrations of the vapor. The characteristic which renders it non-potable is quite similar to that of acetone, to which latter substance it is undoubtedly oxidized in the body on ingestion.¹⁴ On account of this very favorable lack of serious physiological effects from handling, it seems most probable that in making shellacs, varnishes and other solutions, where the spontaneous evaporation of the solvent is an important item, the use of isopropanol will replace that of methanol, which in the past has caused many unfortunate accidents.

GERMICIDAL ACTION

Furthermore, the germicidal action of the higher alcohols has been claimed to be greater than that of ethyl alcohol. Therefore, after proper experimentation has determined the safe limits of application, it would seem to offer a wide field of usefulness in hospitals in many forms of surgical work, and also in dental practice, to provide a safe and accessible sterilization agent. Ethyl alcohol has been used for this in the past,

but unfortunately the present stringent regulations make it inaccessible to many who would desire to use such a material for strictly legitimate purposes.

CHEMICAL APPLICATIONS OFFER INTERESTING POSSIBILITIES

In strictly chemical applications the isopropanol does not compete so directly with the other alcohols, but offers a new material to work with, which will undoubtedly be found to have its own peculiar advantages and characteristics. Through this substance the isopropyl radical will become available for all kinds of synthetic work. At this time there is a very incomplete knowledge of the characteristics of isopropyl derivatives in the dyestuff, pharmaceutical, perfumery and other fine chemical industries. That the isopropyl derivatives will have a somewhat different color, solubility, stability, odor or physiological effect is assured, and to employ this knowledge, which is mostly yet to be gained, will require much research and many years for its fullest development. One large class of naturally occurring substances—namely, the terpenes—contains an isopropyl or modified isopropyl group. The possibility of producing any of these commercially by synthesis is now surely advanced through having a reliable source of this characteristic radical available.

Among the largest uses of all the other commercial alcohols is the preparation of their immediate derivatives which possess even a greater value—e.g., formaldehyde from methanol, ether from ethyl alcohol, amyl acetate from amyl alcohol, etc. The commercial value of the direct derivatives of isopropanol are as yet largely unknown, although that of acetone, the simplest and most direct one, is already fully established through its production from other sources. The commercial possibilities of isopropyl acetate, isopropyl chloride, isopropyl ether and the many other similar products, whose chemistry is already worked out in the older literature, are attractive indeed, and these materials are now waiting for the opportunity to be of service.

(Part V, dealing with ethylene chlorhydrin and ethylene oxide, will be published in a subsequent issue.)

Radium Production in Czechoslovakia

There is a large radium content in the uranium ore found at Jachymov, in Bohemia, near the frontiers of Saxony, reports Trade Commissioner Breed in *Commerce Reports*. Although the radium production in the United States is greater as to quantity, the ores of Jachymov are richer in quality. The known supply of radium in the Jachymov district will last for 20 years at the present rate of production and there are three large mines which are not yet prospected as to depth and in which the veins of ore widen as they are followed deeper.

The Jachymov mines passed in 1912 into the possession of the Austro-Hungarian Government. They have now become the property of the Czechoslovak Republic. The annual quantity of radium produced amounts to about two grams. The net profits to the government expected for the current year is about 3,500,000 crowns, which, of course, has less foreign exchange value than the pre-war profits. As the earnings from the radium mines of the republic are looked upon as a possible source of much profit to the government, projects are under way for electrifying the shafts and millhouses as well as enlarging and modernizing the entire plant.

¹⁴For a more precise description of the pharmacological action of alcohols see Francis and Fortescue-Brickdale, "The Chemical Basis of Pharmacology," 1908, pp. 91-92. Sollman, "A Manual of Pharmacology," 1918, also treats of this matter.

Physiological and Histological Studies on Flayed Skins*

Importance to Leather Manufacturer of a Knowledge of the Structure of Untanned Skins—Principal Divisions of the Corium—Elastic Fibers and Their Function—Experiments Showing the Value of These Observations in Studying the Mechanism of Bating

BY ALFRED SEYMOUR-JONES

THE leather industry and the veterinary profession are unfortunate in not possessing any literature dealing with the histology of animal skins. The published researches of Ranvier, Koelliker, Schaefer and others are devoted to the histology of the human skin, or part of it. Although their results are of material aid and value in enabling one to understand the physiology of animal skins, the variations in the physiological structure of these latter, according to the environment, breed, feed, habitat, etc., of the animal, are so great and marked that it is impossible to apply the work of Ranvier and others, except on general principles. This will at once be apparent if one compares the skins of such mammalia as the elephant, sheep, whale, seal, ox, rabbit, etc., or of reptiles, such as the alligator, lizard, etc.

While it is not proposed in this short paper to describe the histology of all, or even a modicum, of the skins entering into the art of leather manufacture, an endeavor will be made to cover some part of the ground by enunciating general principles which are the result of my researches, in the hope that by so doing it may be possible to throw some light on the causes for certain operations within the tannery.

The skin consists of two main divisions, the epidermis and the corium. The epidermis is entirely composed of keratins and their derivatives. The corium consists principally of collagen, keratins, elastin and fats.

The first act of the tanner is to remove the hair from the skin. In doing this the epidermis is removed as well, though it has not yet been practicable to remove entirely the epidermic products from within the corium, such as hair roots, hair follicles, sweat ducts and glands, etc.

The epidermis and hair being removed, there remains the corium, commonly called the "pelt." The tanner's next act is to remove the adhering flesh from the inner side, which is the *panniculus adiposus*, loose connective tissue joining the skin to the animal's body and which forms the flaying line.

The corium or pelt is now ready for examination. It is a most complex organization, possessing four distinctly different features, structural and chemical, of supreme interest to the producer of sound leather. The four divisions I shall term, pending the suggestion of more appropriate titles: (1) Grain membrane. (2) *Cutis minor*. (3) *Stratum adiposum*, or fatty layer. (4) *Cutis major*, or leather skin.

The grain membrane may be identified with the *membrana propria* observed by human skin physiologists, and is the same membrane which may be seen at the entrance to every opening into the body where the white

skin ends. Klein and Noble-Smith, in their "Atlas of Histology," refer to it as follows: "The boundary between the *stratum Malpighii* of the epidermis and the superficial part of the corium is represented by a fine but distinct membrane structure, basement membrane, which is very conspicuous in preparations stained with dyes. While in some instances it appears as a bright substance separating the deepest layer of epithelial cells from the corium, in others it takes the staining very readily, and, in fact, is made up of the individual cells which have undergone a chemical and morphological alteration. The basement membrane, then, is a direct product of the deepest layer of the epithelium, and its several constituent elements are comparable to the footplate of the deepest columnar cells of the stratified epithelium." That observation is a sound one.

The grain membrane varies in thickness and texture according to the breed of animal, varying, when dry, from 0.001 in. upward. It must be considered as much a part of the corium as it is of the epidermis, being partly keratinous and partly collagenous, and containing a comparatively large proportion of elastin. If a piece be boiled, very little gelatin is obtained; so little is it that the membrane undergoes very slight alteration. To the leather trade it is a valuable feature, and it is the aim of every manufacturer to maintain it intact and uninjured. It would appear to derive the bulk of its keratin from the roots of the basal epidermic cells. These cells are not cemented or glued to the grain membrane, but are attached by minute and innumerable fiber roots, to which the title "young keratin" may rightly be applied, to differentiate them from the harder keratin of the epidermis. When unhairing has been performed with milk of lime, only then these roots dissolve at the point of contact of the grain membrane and the epidermis, producing a glossy sheen called hyaline, or hyaline surface. Unfortunately it is seldom to be seen on the bellies of a skin, but is most marked on the back down the spinal area. Dyers of skins have been puzzled why the color is lighter on the back than on the bellies; this is due to the unequal distribution in thickness and density of the hyaline. Where and when the skin has been unhaired with pure sodium sulphide, or the limed skin has been treated to a bath of sulphide solution before bating, the keratinous hyaline is cleaned away. It is well known that sodium sulphide produces a coarser and rougher feel on the grain of the pelt compared with skins treated with lime alone. In this case the sulphide not only dissolves the hyaline but attacks the basal cell roots of young keratin penetrating the grain membrane.

The collagen content of the grain membrane would appear to be limited to the terminal white fibers of the *cutis minor* which tie themselves into the grain membrane. A large constituent appears to be elastin or its

*Paper presented before the Division of Leather Chemistry at the sixty-second meeting of the American Chemical Society, New York City, Sept. 6 to 10, 1921. Published by permission of the American Chemical Society.

equivalent, and it is because of this that it requires suitable treatment to prepare it to receive any tannage.

The grain membrane is soft and thin in the soft fur or wool-bearing animals, but increases in thickness and harshness as the hairs become coarser and thicker. This latter fact especially applies to certain classes of goat-skins. The epithelial pavement of the grain membrane is sometimes so thick as to form overlapping scales, giving a beard effect after unhairing. Beard is also caused by the coarse hairs either breaking off at their junction with the skin, or, when removed, they may have left behind, but broken off at their junction with the skin, the thick and horny hair follicle (epidermic). This and the broken off hair protrude sufficiently to cause the rough feel called "beard."

CUTIS MINOR

The *cutis minor* is the *cutis vera* of the human skin histologist. I suggest that the entire flayed skin or corium is the *cutis vera*, or true skin. The *cutis minor* is only from 5 to 20 per cent of the entire corium substance. But, small as it is, it is the most vital part of the whole, both pathologically and from the leather-making standpoint. The *cutis major* is radically different in every way and functions and forms a clearly separate layer. The *cutis minor* begins with the papillary layer and ends at the *stratum adiposum*, or fatty layer, in which the hair root bulbs repose and wherein are the sudoriferous glands with their ducts ascending through the *cutis minor* via the epidermis to the exterior. The *cutis minor* is composed of white collagenous fibers, yellow elastic fibers, *erector pili*, or hair-erecting muscles (which belong to the involuntary type), nerve fibers, sudoriferous ducts, blood capillaries and hairs with their accompanying epidermic follicles. It will be seen that it is a very complex organization.

STRATUM ADIPOSUM, OR FATTY LAYER

If the works of Koelliker and others are referred to and the drawings of vertical sections of skin examined, it will be seen that, perhaps inadvertently, the third layer has been called the *panniculus adiposus*. Obviously this is a mistake, as that layer is the loose connective tissue between the skin and the animal body, which enables the pelt to be flayed conveniently, and is commonly termed in the leather trade "the flesh," the substance which is removed from the inner side of the skin. Assuming that this is admitted, it becomes necessary to give a new title to this layer, and, as it is mainly composed of fat cells in groups, like bunches of grapes, it seems that *stratum adiposum* fits the case.

CUTIS MAJOR, OR LEATHER SKIN

The *cutis major* is to be identified with the *pars reticularis*, or leather skin. It is the major part of the whole, and is composed of large, thick white fibers, built up of numerous fibrils, traveling in every conceivable direction, crossing, criss-crossing, intertwining and sometimes splitting to become parts of other fibers. This apparently unreasonable arrangement appears to defy an explanation. It would seem that it is of set purpose. This layer is devoid of elastic fibers. It is collagenous, contains the usual blood vessels requisite for its nourishment and that of the regions beyond; likewise the nerve fibers pass through it. It is an almost inextensible layer, lying next to the body, growing as the beast grows; but it fails to reduce its area with the decline of the beast. Its functions would therefore appear to be

to act as a limiting and protecting coat for the body and a non-expansile base upon which the fatty layer and the *cutis minor* can rest.

Having rapidly reviewed the general structure of skin without going into minute details, the grain membrane and the *cutis minor* will be discussed in greater detail.

THE CAUSE OF GRAIN

Consider first the papillary layer lying immediately under and attached to the grain membrane. If a section be made of a raw skin in the hair, it will be seen that below the epidermis the skin shows a line of ridges and indentations. These represent depressions and elevations in the skin; they contain nerve endings and blood capillaries. If a section be made after unhairing, then they will probably have disappeared, or can be traced only with difficulty. This is due to the epidermis filling up the hollows or valleys; while appearing flat on the surface, the epidermis is thicker in the hollows and thinner on the apexes. The epidermis is a non-extensible quantity, holding the papillary layer intact, but, once the support has been removed, the grain membrane and papillary layer fall flat and expand in proportion. This layer calls for little comment from the leather standpoint, except to say that where the papillæ exist, as in the case of goatskins, they are the cause of the pretty morocco grain. Their almost entire absence in ox, sheep and various other skins is the reason for their not "graining."

ELASTIC FIBERS AND THEIR FUNCTIONS

The *cutis minor* is very largely composed of white fiber bundles composed of fibrils, whose arrangement differs from that of their colleagues of the *cutis major* inasmuch as they are erect or nearly so. Except in certain instances they do not anastomose like those in the *cutis major*. If a section be examined after treatment with weak acid, it will be seen that they are in minute bundles, each bundle being choked by bands. These bands are elastic fibers. Descending from the grain membrane, they permeate the entire white fiber structure of the *cutis minor*, encircling the bundles, gathering the fibrils into bundles, sometimes dividing neighboring bundles, and attaching fibrils to other bundles. They are seen massed, encircling each hair follicle, and alongside are white fiber bundles which do not stand erect, but encircle the hair follicle with the elastic fibers keeping company. They spread all through the *cutis minor* in a marvelous network, terminating their activities only around the bases of the hair roots. According to their character, thick or thin, and their quantity, so is the firmness of the pelt.

It is interesting to note that the elastic fibers appear to possess selective capacity because they are never to be seen bunching the masses of blood capillaries or interfering with the *erector pili*, or any other part of the *cutis minor* organization except the white fibers. What is then their function? It naturally suggests itself. As the white fibrils are disposed more or less erect and are very densely packed together, they require something to maintain them in their erect attitude. This appears to be the function of the elastic fibers. They are under tension, and keep the whole of the *cutis minor* under tension, thus forming a cushion, keeping the hairs and their follicles in their correct positions and the groundwork clear for the other organs to function, giving free movement for the life-giving lymph sub-

stances. They enable the *cutis minor* to become a cushion to the *cutis major* and the animal body. Press the skin gently in life and it promptly recovers on removal of the pressure, due to elastic fiber action.

These statements are easy of proof. It will have been noted by tanners that the grain membrane is slightly larger after unhairing. Now split a skin through the *cutis minor*; this cuts through the elastic fibers, releasing them from tension. The white fibers then more or less collapse, the grain split expands several inches in area, but the flesh split remains exactly the same area. J. T. Wood, of Nottingham, at my request very kindly measured a number of split grains and their flesh. He states: "The grains averaged 86 sq.ft. to the dozen, and the linings or flesh, fully stretched, 71 sq.ft. to the dozen." But that is not the full area of the grains; they are still more or less bonded by the elastic fibers. Again Mr. Wood says: "When the grains are puered, they come out considerably more, because they can be stretched without springing back." Why do they not spring back after puering? The answer is the answer to the question, "Why do we puer?"

EXPERIMENTS ON THE MECHANISM OF BATING

Over 2 years ago I set out to find the answer by making a series of practical experiments. In order that there should be no question as to the accuracy of the experiments and results and having no available means to carry them out personally, Mr. Wood was asked if he would carry out certain experiments without indicating the object, though he, being an expert, quickly realized their aim.

First a sheepskin pelt was split and the grain and flesh were divided down the spine to make two halves of each. Grain A was delimed and puered with trypsin, because this enzyme acts freely on elastin, while grain B was simply delimed. Similar treatment was meted out to flesh A and B. The deliming was carried out with weak acetic acid. The trypsin-treated grain, after tanning in sumac, was all such a leather should be—color, texture, etc., excellent. Its substance in the crust state was 0.008 in., CaO content 0.6 per cent.

The grain merely delimed, after sumac tanning, was of a brownish hue, with the grain tucked into fine nodules, texture harsh, lacking ideal qualities. In the dry crust condition its substance was 0.013 in., and CaO content 0.9 per cent.

The lime content is a negligible quantity and does not offer the true explanation for the great difference. The trypsined grain shows a loss in substance, the difference in the two grains being approximately 50 per cent. Something has been dissolved out. As trypsin attacks elastin vigorously, it may be assumed that the elastic fibers have undergone a change, especially as the grain membrane is so soft and flexible.

The trypsined flesh on casual examination does not appear to vary in any marked particulars from the acid delimed flesh, but on testing equivalent parts for substance, it was seen that the trypsined flesh was thicker and also weighed more. CaO contents were 0.72 and 0.82 per cent respectively. On analysis the following results were obtained:

	Flesh A Per Cent	Flesh B Per Cent
Moisture.....	14	14
Mineral ash.....	1.6	1.9
Hide substance.....	43.1	45.6
Tanning matter.....	41.3	38.5

Here lies the explanation. The trypsined flesh has lost some of its hide substance (probably mucin), which has been replaced with the heavier weighing tanning substance filling up the waste areas opened up. On washing out the free tan, the flesh fell in substance to lower than the delimed flesh. While trypsin attacks elastin preferentially, it is quite capable of attacking the young collagen substance or mucin, but does not digest collagen unless previously suitably treated.

The trypsined flesh is slightly coarser of fiber than the delimed. This is to be expected. What the experiment does prove is that it is not at all necessary to puer the flesh unless loss of hide substance is desired. As a chamois-making proposition, or for making imitation suèdes, the delimed flesh is far superior. As it appeared to be unwise to puer the flesh when it is desired to retain as much substance as possible, a further experiment was undertaken to prove whether it was possible and practicable in a whole skin to puer the grain membrane and *cutis minor* only. Mr. Wood, at my request, anointed a sheep pelt, after acid deliming, with a trypsin paste on the grain membrane side only. After laying out flat on the floor until it was considered "down," it was scudded and sent direct into sumac tan. The result was a perfect full-substanced tanned skin of beautiful color. There was no loss of *cutis major* substance. The skin was degreased with naphtha after tanning. It will be noted that no bran drench was employed.

The last experiment was repeated, this time on a light medium substance goatskin, subsequently chrome tanned and finished as glazed kid. Here the grain is silky and mellow without the least evidence of internal looseness, texture excellent, and substance has been maintained. The only loss of substance in either the sheepskin or the goatskin occurs in the collapse of the *cutis minor* structure due to the loss of its binding fibers.

ELASTIN REMOVED BY BATING WITH TRYPSIN

So far as these experiments go, they illustrate the fact that it is the grain membrane and the *cutis minor* alone which require puering or bating, and it is wise to confine the bating action to that part of the skin alone. But they are not conclusive as to what it is that has "collapsed" under the treatment. To test this it is necessary to make skin sections at different stages of the process of bating. It must be pointed out that the method of testing skin sections as to the presence of cells, collagenous fibers, yellow elastic fibers, etc., is by applying different staining materials. For example, collagen has a special affinity for acid fuchsin and water blue, while elastin has a strong affinity for acid orcein. Sections made before and after bating clearly showed that the elastin had disappeared; at least, if it was present, it had so altered its character as to be void of elastin proper and unresponsive to acid orcein tests.

Most interesting confirmatory evidence has come from the laboratory of R. F. Gallun & Sons of Milwaukee, in a paper by J. A. Wilson, entitled "The Mechanism of Bating." This paper was accompanied by excellent photomicrographs showing sections of calfskin untreated with trypsin, and after 6, 20 and 24 hours bating with trypsin. The unbated section exhibits the elastic fibers massed. The three successive sections, varying as to time of treatment by trypsin, show the gradual disappearance of the elastic fibers until finally none are to be

seen. This then furnishes practically conclusive evidence of the part played by trypsin on the elastic fibers.

ACTION OF OTHER BATING METHODS

But trypsin or its equivalent is not the only material employed in bating. Our forefathers employed what has been called the "river process," the skins being left in a soft water running stream until they were soft and flaccid. Exactly what happened is not at all clear. Then the bran drench alone is used as a bate with great success. Here there can be no question of the presence of trypsin, it being entirely composed of fermentative acids. This acid process is the same as the old ooze employed by tanners in bygone days, and the same as the sour suspenders of modern tannery practice and the process invented by Dr. MacBride of Dublin over a hundred years ago in using vitrol to hasten tanning. The pickled sheepskins from New Zealand and Australia cannot be said to receive any bate prior to pickling, and yet they tan soft grains, like all pickled skins will. The acid bate is an alternative to trypsin. Pfeuffer, Mall and others have pointed out that acids and alkalis break up the elastin into globules, and eventually dissolve it. This implies inverting the elastic tissues along the line of their growth. Ranvier has shown that the development of elastic tissue is by deposition of fine granules of elastin, forming themselves into monoliform rows of fibers; these are inclosed in a sheath, the whole containing the substance called "elastin." The granules or cells grow or are converted into what we know as elastic tissue. The acid or alkali process mentioned causes the process to invert, with the consequential release of the "elastin" and the grain membrane is capable of receiving tanning.

OPPORTUNITIES FOR FURTHER RESEARCH

This only touches on the fringe of one of the most perplexing yet important subjects of the leather industry. Yet enough has been said to make it worth while for the subject to become a valuable line of research. No process of leather making is more disgusting, or attended with more unpleasant consequences, or causes more unsound leather to be made and money lost, than the bating process. No money is spared to tan a skin soundly, but such is wasted when the very foundation is wrong, and I submit that a case has been made out for more extended research into the foundation processes of the leather industry.

It has been impossible to describe the structure of all the varied skins entering into the art of leather manufacture, or to speak of its chemical side.² But sufficient has been said to illustrate the assistance which a proper use and appreciation of the microscope can be in elucidating the problems, amounting to mysteries until they are solved, which surround leather production. The field for research is larger in this than in any other industry, and the rewards from patient successful research cannot be estimated in cash values. The golden key to the mysteries lies hidden, waiting the advent of the finder, and he who will devote himself patiently to research, however long it may take, will discover that key fitted with suitable wards ready to open unto him his inheritance. Successful research is the highest rewarded effort in this life.

Wrexham, North Wales.

²The chemical metabolism within the skin organization, differing as each successive layer does from its neighbor, yet called under the one term, collagen (glue producing), is an almost untrodden field for research.

Legal Notes

BY WELLINGTON GUSTIN

The Gaulin Patent, Claim 7, Held Valid, but Not Infringed

In the recent case of Marston-Gaulin Manufacturing Co. vs. Wright-Ziegler Co. and others, the Federal Circuit Court of Appeals, First Circuit, held that the Gaulin patent No. 756,953, claim 7, for an apparatus for intimately mixing liquids, was valid but not infringed. (271 Fed., 391.)

The patent was issued to August Gaulin for an "improved apparatus for intimately mixing milk and other liquids more or less resembling it by means of the action produced by the passage of liquids more or less heterogeneous under considerable pressure through very small orifices." The claim in issue was No. 7 and follows: "In a machine of the class described, an element having a re-entrant conical surface, a complementary conical element to fit the same, and means to force milk between them, substantially as described."

Defendant contended that the patent was invalid and non-infringed. In two previous suits on the patent it had been held valid on another claim, hence the court assumed that the approved apparatus disclosed inventive thought and was patentable.

The plaintiff contended that although a re-entrant conical valve is old, the combination is new and the claim valid, even though it does not state whether the surfaces of the conical valve, when in operation, yield one to the other, rendering the orifice of the valve variable, or whether the surfaces are rigidly fixed, rendering the orifice invariable, and that the plaintiff is at liberty, for the purpose of making the combination workable, to employ such means as may be disclosed in the specification for holding and adjusting the surfaces, or any suitable means that is common.

CLAIM OF THE DEFENSE

The defense was that if the claim be valid its language must be interpreted to mean that the conical surfaces are yielding and thus afford a variable orifice; that if the surfaces are non-yielding so that the orifice, when the device is in operation, is fixed or invariable, as the plaintiff said the claim should be interpreted, the claim would not be based upon the invention which Gaulin conceived, but upon a device the principle of which he disclaimed in his specification.

DECISION OF THE COURT

However, the majority opinion of the court held that the claim was valid; that read in the light of the specification, the language of the claim, where the conical surfaces are spoken of and are required to fit one with another, and between which the liquid is to be "forced, substantially as described," means that the liquid is to be forced between surfaces which fit closely one to the other and permit the liquid to be forced through because of their yielding quality.

As thus construed, the defendants do not infringe the claim, for the conical surfaces of the defendants' device are not yielding, but fixed, and the orifice is invariable, said the court.

Note on Mushet Steel

By A. H. D'ARCAMBAL

Metallurgist; Pratt & Whitney Co., Hartford, Conn.

WE RECENTLY conducted some tests on a 1 3/4 x 3/4-in. bar of Mushet steel received by the Pratt & Whitney Co. about 30 years ago. The analysis of this material was as follows:

	Per Cent		Per Cent
Carbon.....	2.38	Chromium.....	1.12
Manganese.....	1.73	Tungsten.....	4.80
Silicon.....	1.15		

The chromium content is considerably higher and the tungsten content slightly lower than the Mushet steel¹ used by Taylor in his classical experiments. Brinell hardness on this material as received was 512, somewhat high according to present ideas, but as tools were always forged from this material, this hardness was not detrimental. Referring to Fig. 1, the micrograph of the material as received shows large plates of carbide imbedded in the martensitic-troostitic matrix.

Three small pieces were cut from the bar, one quenched from 1,500 deg. F. (816 deg. C.) into oil (the temperature usually given Mushet steel), the second piece quenched from 1,900 deg. F. (1,038 deg. C.) into oil, and the third piece from 2,200 deg. F. (1,204 deg. C.) into oil. After hardness tests and micrographs were made of each of these pieces, they were drawn to 1,000 deg. F. (538 deg. C.), air-cooled, again tested for hardness, and photographed. Hardness results were:

Quenching, Deg. F.	Temperature, Deg. C.	Medium	Drawing Temp., Deg. F.	Drawing Temp., Deg. C.	Sclero-scope	Brinell	Micro-structure
1,500	816	Oil			95	652	Fig. 2
1,500	816	Oil	1,000	538	80	512	Fig. 3
1,900	1,038	Oil			53	364	Fig. 4
1,900	1,038	Oil	1,000	538	87	600	Fig. 5
2,200	1,204	Oil			50	364	Fig. 6
*2,200	1,204	Oil	1,000	538	95	652	Fig. 7

* The first piece given this treatment broke into several small pieces while being tested for hardness and a new piece had to be given the same treatment.

Figs. 2 to 7, containing these micrographs, show that the 1,500 deg. F. (816 deg. C.) quench gave a martensitic structure, most of the carbides being in the free state. Drawing at 1,000 deg. F. (538 deg. C.) produced a martensitic-troostitic structure with a corresponding decrease in hardness.

The 1,900 deg. F. (1,038 deg. C.) treatment produced an austenitic structure, containing a little martensite. This higher temperature also dissolved more carbides. Drawing to 1,000 deg. F. (538 deg. C.) gave a martensitic structure, greatly increasing the hardness.

¹C, 2.40; Mn, 1.90; Si, 0.71; Cr, 0.49; W, 5.62.

FIG. 1. BAR AS RECEIVED. X 500. ETCHED 3 MIN. WITH NITAL

We attempted to quench the remaining piece from 2,300 deg. F. (1,260 deg. C.), but due to the analysis of this material, principally the high percentage of carbon present, the material began to soften at 2,200 deg. F. (1,204 deg. C.) and was therefore quenched at this temperature. The micrograph shows the material to be overheated, liquefaction and resolidification of the carbides at the grain boundaries taking place. The structure is austenitic and entirely non-magnetic. Drawing to 1,000 deg. F. (538 deg. C.) gives a martensitic structure, the large grain boundaries remaining unchanged, but this high drawing temperature made the steel so brittle it broke into several pieces under the Brinell ball. The scleroscope and Brinell readings nearly doubled after this high draw.

It would appear from the results obtained in these experiments that the best treatment for this steel would be to quench from 1,900 to 2,000 deg. F. (1,038 to 1,093 deg. C.) and draw back to from 1,000 to 1,050 deg. F. (538 to 566 deg. C.). Taylor in his experiments showed that Mushet steel did not respond to the Taylor-White treatment in as high a degree as some of the other self-hardening steels, due to the low chromium content of the Mushet material.

Greensand as a Source of Fertilizer Potash*

By R. NORRIS SHREVE

GREENSAND occurs very extensively in the states of New Jersey, Delaware, Maryland and Virginia. The commercial beds carrying from 5 to 7.5 per cent potash, however, are chiefly within the state of New Jersey. When it is realized that "a 20-ft. bed (of 7 per cent K_2O material) that covers a square mile should yield 1,500,000 tons of potash; a 20-ft. bed of 5 per cent greensand should yield 1,000,000 tons to the square mile;" and when it is further remembered that "there are many square miles of greensand containing 7 per cent of potash and perhaps hundreds of square miles containing 4 or 5 per cent," it is easy to see the commercial possibility of greensand as a large potential source of potash for fertilizer or other use.

LOCATION AND CHARACTER OF GREENSAND DEPOSITS

The greensand deposits are accessibly located near the potash-using localities; the beds are cut by railroads in a number of places, and they are also accessible to water transportation. Furthermore, the greensand is near the surface, so that cheap methods of mining by steam shovel or dredging can be employed. Mineralogically greensand is a mixture of the potash-carrying glauconite with more or less sand, shells, etc. The separation can be made magnetically, and this scheme is practical on a large scale to concentrate the beds with lower potash percentages up to 6.5 to 7 per cent potash.

Commercial beds of greensand contain around 7 per cent of potash, 50 per cent of silica, 18 to 23 per cent of iron oxides (as Fe_2O_3), 7.5 to 10 per cent of alumina, 3 to 7.5 per cent of magnesia and small amounts of lime, soda, sulphuric acid and phosphoric acid. Often the soda is practically absent, and chlorine is always very low.

Forty and more years ago the greensand was mined very extensively by the local farmers of New Jersey and spread on their fields with very satisfactory results for that time. However, the potash and phosphoric acid in the greensand are so slowly available that this practice was not economical in competition with the more concentrated and more readily available fertilizers later introduced.

A number of potassium compounds suitable for fertilizer use can be made from greensand, and among these potassium nitrate offers the most advantages.

The process that the Eastern Potash Corporation has used for 2 years at its small manufacturing plant at Jones Point, N. Y., and which will be used at the large plant now under construction on the Raritan River, near New Brunswick, N. J., involves the initial manufacture of caustic potash by treating the greensand with lime in the presence of water and at a temperature of about 470 deg. F. for 1 hour.

Caustic potash is a very reactive compound and can be easily changed into various potassium salts and in such a way as to preserve also the very valuable hydroxyl part of the caustic potash—in the form of caustic soda for example.²

The reaction was initially carried out as follows: 1302 g. of a commercial caustic potash from greensand, analyzing 42.6 per cent KOH, was placed in an iron kettle and 912 g. of commercial nitrate of soda, analyzing 1.65 per cent KNO_3 and 94.2 per cent $NaNO_3$, was introduced. This was sufficient to produce theoretically 1,000 g. of potassium nitrate.

The reaction was carried out by heating at 105 to 110 deg. C. for 30 minutes, and then allowing to cool. The potassium nitrate was separated and washed with alcohol, weighed and analyzed:

Dry weight of potassium nitrate recovered, grams.....	957
Weight of mother liquor, caustic soda (37.5 deg. Bé.), grams..	90
Weight of alcoholic wash, grams.....	242
Analysis of Potassium Nitrate	
KNO_3 , per cent.....	97.3
NaOH, per cent.....	0.8
Na_2CO_3 , per cent.....	2.0
NaCl, per cent.....	0.1

The recovery of potassium nitrate was 91.6 per cent on this first crop, when the 15 g. of potassium nitrate contained in the original nitrate of soda is subtracted from the weight obtained.

A few more per cent of potassium nitrate is recovered from the mother liquors by subsequent concentration and crystallization. The final mother liquor is 50 deg. Bé. caustic soda carrying about $1\frac{1}{2}$ to 2 per cent K_2O and about twice this per cent of N_2O_5 . During the process of solidification of this caustic soda the N_2O_5 can be largely removed, resulting in a caustic soda of commercial quality.

On a large scale, using centrifuges and water washing, a potassium nitrate of from 95 to 97 per cent purity is easily obtained without recrystallization, and this potash salt will be offered to the fertilizer trade.

POTASSIUM NITRATE DIRECT FROM GREENSAND

As the process will actually be carried out, the sodium nitrate will be added to the digestion mixture of greensand, lime and water, because of the very valuable accelerating action of the nitrate upon the decomposing action of lime on the greensand,⁴ wherein the yield of converted potash is increased from 60 to about 80 per cent.

Upon concentration of the caustic liquors, the potassium nitrate crystallizes out, leaving the caustic soda. For every 100 tons of potassium nitrate manufactured there will be obtained about 40 tons of caustic soda of commercial grade. Consequently the importance of the caustic soda production in cheapening the cost of the potash compound is very apparent.

The plant under construction will produce about 20,000 tons of K_2O per year, and approximately three-quarters of this will be marketed as potassium nitrate, thus furnishing about 34,000 tons of 95 per cent quality.

Opinion of competent fertilizer experts is that the only reason that potassium nitrate has not come into more extensive use in the fertilizer trade is on account of its price. As the intention is to sell the potassium nitrate on the basis of the current market prices for the potash and the nitrate contents, the past objection will no longer prevail.

Furthermore, because of the concentration of two fertilizer ingredients in the same chemical, there will be a large saving in transportation charges, which is an important item these days.

To be sure, the ratio of nitrogen to potash will need to be varied as occasion demands.

New York City.

Electric Iron and Steel Plant for Brazil

This Unique Installation, the First of Its Kind, Includes Two Swedish Type Pig-Iron Furnaces, Two Bessemer Converters, a Ludlum Steel Furnace and Two Merchant Mills, All Driven by Electric Power and Heated by Electric Energy

By N. A. V. PAULSSON
Consulting Engineer, Corning & Co.

WHAT is thought to be the first all-electrical plant making steel from iron ore has been designed by Corning & Co., Inc., of Albany, N. Y., and is now under construction in Brazil. It also bears the distinction of being the first complete steel plant in Brazil—a country which has been credited with having the greatest reserves of iron ore in the world. At present there are a few very small, primitive blast furnaces making charcoal iron, but their combined output is not more than 40 tons of pig iron per day. The State of São Paulo also has a steel foundry, with two small electric furnaces melting scrap, and a small rolling mill where faggoted scrap is rolled into bar iron. Consequently the new plant is the first step toward supplying a domestic market which in 1919 imported 40,000 tons of merchant bar and sheets and 135,000 tons of wire, tin plate, rails and pipe.

TO ABSORB SURPLUS POWER BETWEEN SEASONS

Electric steel making in Brazil will be the result of an attempt to utilize electrical generating capacity during the "off-peak" season. A power company called the *Empresa Força e Luz de Ribeirão Preto* had built some hydro-electric plants and gradually spread out a network of transmission lines serving a large number of coffee plantations. Each of these required in the neighborhood of 100 hp. to drive its machinery for cleaning the hulls from the coffee bean, but a large part of this demand existed only during June, July and August, and unfortunately these months are the dry season, when there is a minimum stream flow. During the remainder of the year a considerable amount of developed and an enormous amount of undeveloped horsepower was available for use, but no user appeared. Consequently the power company set about a search for some industry—any industry—which would have a large consumptive demand for electricity, which could run at a low rate, or be entirely shut down for two or three months each year, which would increase the population of the locality and which would turn out a product readily salable in domestic or foreign markets. Steel manufacture seemed best to meet these requirements, so an affiliated company, the *Cia Electro Metallurgica Brasileira*, was organized to construct and operate such a works at Ribeirão Preto, a small town near the center of the power network.

Ribeirão Preto, as can be seen from the map, Fig. 1, is in the northern part of the State of São Paulo, about 250 miles inland from Santos. Entering the latter port, one boards the English-owned São Paulo Railway Co., of broad-gage and excellent equipment, which climbs up the steep border of the inland plateau through São Paulo to the rail-center at Campinas. From here inland extends the *Cia Mogyana de Estrado*

do Ferro, of 1-meter gage, through rolling country, well developed, with good communications and almost exclusively given over to coffee plantations. Ribeirão Preto is in the midst of such a region, at 1,500 ft. elevation. Ore will come about 75 miles from an iron mountain called Morro do Ferro, just over the line in the State of Minas Geraes. Eventually the steel company will own a direct road between mine and smelter, but at present the ore will be brought to the plant over narrow-gage (60 cm.) English-owned road connecting with the main line at São Simão.

Morro do Ferro is a huge deposit of hematite, covered with broken ore—canga, so called—which analyzes 65 to 67 per cent iron, the equivalent of 93 to 96 per cent Fe_2O_3 . It is therefore of unusually high tenor. One sample analyzed in this country showed Fe_2O_3 , 90.9; FeO, 2.9; MnO, 0.54; SiO_2 , 5.4; S, 0.00; P, 0.022. Pig iron reduced from a sample shipment to the United States, using a pit furnace and charcoal, analyzed Fe, 95.3; Si, 0.06; P, 0.02, and C, 4.5. A considerable tonnage of this loose ore may be had for the trouble

FIG. 1. MAP OF TERRITORY SURROUNDING SANTOS

FIG. 2. GROUND PLAN OF IRON AND STEEL PLANT

of loading it on cars; quarrying operations will begin later.

At present 5,000 kva. is available for use in the iron and steel plant, and it has been designed for this limiting condition, as will be detailed later. The power company has started construction of a new power house, developing 12,000 kva., which will be for the exclusive use of the smelter; the plans (Figs. 2 to 4) permit of any extension demanded. Machinery to be installed is:

Two Swedish type furnaces, 1 standby, kva.....	3,000
Two 6-ton bessemer converters (blowing engine for one), kva.....	700
One 6-ton Ludlum steel furnace, max., kva.....	1,500
One 16-in. rolling mill, kva.....	500
One 10-in. rolling mill, kva.....	500
Miscellaneous 220-volt power for motors, cranes, shops and lighting, kva.....	400
	6,600

This tabulation shows that it will not be possible to operate all units simultaneously—indeed, the plant is designed having balanced operation not so much in mind as to be the nucleus of a larger plant, and therefore it contains a series of units large enough to operate with undoubted success and economy. Thus, experience has shown that the pig-iron furnaces may be tapped advantageously four or five times a day, each tap yielding about 6 tons of iron. This is transferred immediately to the bessemer converter and blown to steel, an operation requiring not more than 15 to 20 minutes on the iron smelted in 5 hours. Normally the steel will be cast direct into ingots, but if it needs “doctoring” in any way, it will be transferred molten to the Ludlum steel furnace, an appropriate slag made up, deoxidizers and carburizers added, and then it will be cast into

ingots. Cold, low-silicon pig will also be reheated in the Ludlum furnace, and necessary ferrosilicon added before the blow. Such duty on the steel furnace might require 2 hours at most, and would occur but infrequently. Consequently there remains an ample period of time, even during the day shift, when the mills can dispose of the 30 tons of steel produced in the preceding 24 hours without drawing any power when the steel-making department is also making its demands.

ELECTRIC PIG-IRON FURNACE

Exclusive South American rights for the Swedish type of electric pig-iron furnaces have been bought by the Cia Electro Metallurgica Brasileira. Two of them are now being installed (Figs. 2 and 3), each with electrical transformers and complete in all respects. As noted above, only one can be operated, however, until the new power house is completed.

This furnace has been discussed from many viewpoints in the technical press and especially in America by CHEMICAL & METALLURGICAL ENGINEERING, so there is no need of describing the details further, except noting such changes as it has been thought desirable to make to conform to the conditions existing in Brazil. An excellent drawing of the furnace was published in this journal, March 9, 1921, vol. 24, p. 431, by Baron de Geer, which may be referred to.

It has been thought desirable to decrease the diameter and height of the shaft (which, by the way, is hung from the building), because the charcoal avail-

in the open market—in the almost total absence of coal, it is a staple commodity. As circumstances warrant, the company will plant its own eucalyptus forests for a source of fuel. Such is a common practice of the Brazilian railways; eucalyptus culture is quite well understood. The tree matures in 5 to 6 years, having a trunk at least 6 in. in diameter.

ELECTRICAL FEATURES

Current is received at 30,000 volts, 50 cycles, three phase, and will be transformed outdoors to 6,000 volts, whence it is taken by lead-covered underground cables

FIG. 4. CROSS-SECTION OF ELECTRODE CRADLE

to the substation adjacent to the mill building. Each pig-iron furnace has three 1,500-kva. water-cooled General Electric transformers, especially built for this service, whose secondary will deliver any voltage from 60 to 120 volts—smooth curve regulation. Each furnace has six 24-in. carbon electrodes. Adjacent electrodes are connected with the same phase; or, expressed in another way, denoting phases by A, B and C and reading around the circle, the electrodes are connected thus: A, A, B, B, C, C. Such a layout makes for very

FIG. 3. ELEVATION OF STEEL-MAKING DEPARTMENT

able in Brazil is very much denser than that made from the northern conifers, and the charge is consequently less bulky. Brazilian charcoal weighs 15 lb. per cu.ft., while that name in Sweden weighs but 9 lb. Its electrical resistance and other physical characteristics are not so much different as to cause the designers to expect a repetition of the troubles experienced when coke was first used in place of charcoal.¹ Charcoal will be bought

easy busbar connections, offering ample opportunity for interlacing between transformer and electrode, and produces a good power factor.²

An ample equipment in electrical meters is provided for each electrode. Since the electrodes are immersed in the hot granular charge and are fed into the furnace only at intervals as they are consumed at the lower end, control is had by adjusting the voltage impressed on

¹"Electric Smelting of Iron Ore With Coke," by Georg Stig, CHEM. & MET. ENG., vol. 23, p. 29, July 7, 1920.

²"Manufacture of Electric Pig Iron in Sweden," by J. A. Leffler, Teknisk Tidskrift, April 27, 1921.

FIG. 5. CONVERTER SHELLS

any one phase. One operator is assigned to this duty, and if the current becomes unbalanced, the input is adjusted by appropriate changes at the transformer.

Electrodes enter the bosh roof through close-fitting water-cooled copper sleeves, set in the brickwork. Directly above is clamped a solid copper ring, leading in the current. Some distance further back is a ring which not only supports the weight of the electrode, but has ears on each side which fit into channel-iron guides, 16 ft. long and supported by the building. Hung

Charcoal is transported from the charcoal house to the furnace top in 250-lb. buckets, carried on an aerial tramway.

About sixty charges per day of approximately 1 ton each will be made. A single bell is sufficient for such infrequent operation. A small quantity of powdered ore is thrown into the hopper previous to the regular charge, thereby forming a seal which prevents gas escaping and guards against gas poisoning.

Since the steel is to be made in bessemer, it is necessary that it contain at least 0.75 to 1.00 per cent silicon to furnish the requisite heat during conversion. It is also desirable to blow iron containing 1.5 to 2.0 per cent manganese, so there may be some residual manganese. To provide the latter an appropriate amount of manganese ore from some Brazilian source will be a portion of the charge. It is well known that furnace irregularities make it impossible to tap hot high-silicon iron at all times; consequently the Ludlum furnace is expected to prove most useful in increasing the temperature and adjusting the chemical composition of off-runs of iron before conversion.

STEEL MAKING

Two 6-ton bessemer converters shown in Fig. 5, built by the M. H. Treadwell Co., will be installed, one of

FIG. 7. LONGITUDINAL SECTION OF REHEATING FURNACE, AND PUSHER

under these guides at 3-ft. spacings are rollers which cradle the electrode; two pairs of side rollers also help maintain the alignment. Its up-and-down movement is effected by a pair of long screws threaded into the ring mentioned above, the screws being geared together by link chain at the top and hand-operated by ratchet. Fig. 4 shows a cross-section of this electrode cradle.

IRON SMELTING

Ore is brought in from the mine in 14-ton narrow-gage steel gondolas, with swinging side doors, very similar to the familiar ballast car. (These were favored over hopper-bottom cars, since they are a general-purpose car and can easily handle charcoal by merely adding to the height of the sides.) It is discharged from the stockpile into a jaw crusher, reduced to 2 in., and elevated by a counterweighted skip carrying 3,000 lb. to a hopper in the roof of the furnace building. Thence it is drawn into a car on an automatic railway, discharging 3,000 lb. each trip to a chosen storage bin. All these operations are remote controlled.

These ore and limestone bins above the charging floor have a combined capacity of 250 tons. From bin to charging bell, the ore and stone are carried by a jib crane, bearing suspension scales and a large scoop.

which will be kept in standby condition, ready to take metal when the sides of the other require relining or in case of accident. It will be noticed that the mouth is much smaller and somewhat hooded, as compared with

FIG. 6. LUDLUM FURNACE

FIG. 8. PLAN OF ROLLING MILL

the vertical converter common to American plants, a feature necessary to conserve the heat during the long intervals between blows. Transfer of hot pig iron will be made by ladles and overhead cranes. One blowing engine only will be installed, and it will be in use not more than 2 hours out of the 24. It will be driven by a 6,000-volt, 700-kva. synchronous three-phase motor.

Blown steel will be recarburized in the vessel—residual manganese is expected to cut down the needed deoxidizer to a minimum. It is then discharged into a 6-ton ladle, and teemed into solid or split ingot molds, 7 in. square by 4 ft. high, big end up. No stripper will be needed.

A 6-ton Ludlum electric steel furnace (Fig. 6) will be provided as an essential piece of emergency equipment. As noted, it will be in readiness to reheat cold pig, to quiet wild bessemer metal and, in addition, to reclaim mill scrap and on occasion make alloy steel or castings. This furnace, as is perhaps well known, is the original three-phase furnace having its three electrodes set in a row, an oval-shaped, accessible hearth, with doors at each end and a removable roof. The plan, Fig. 2, shows its location alongside the converters; it is commanded by a 6-ton crane. Its electrical equipment is located in the substation immediately adjacent and consists of one 1,500-kva. General Electric transformer, with all necessary instruments and automatic electrode control.

ROLLING MILLS

Ingots are reheated in a long furnace shown in Fig. 7, utilizing excess gas from the blast furnace in three burners, or oil, in case both furnaces are shut down. A rather unique feature is the fact that the roof is air cooled and the air is thus preheated for combustion. A simple pusher is installed to feed the furnace.

Two merchant mills of the conventional type are being installed; the plan is given in Fig. 8. They deserve no special description. The roughing stand is a three-high 16-in. mill, reducing the ingot to a 2-in. square. Finishing is done in a 10-in. mill, stands three-high, and the finishing stand two-high. Rolls for making rounds, flats, squares and various types of merchant bar and concrete reinforcement, as well as light angle iron, will be provided. Each mill will be driven by a 6,000-volt, 500-kva., three-phase induction motor.

The government is naturally interested in the beginnings of this industry, financed as it is exclusively by

Brazilian capital, and has permitted the entry of all the construction material duty free. All of the material has been shipped; construction of the plant is actively under way, and it is hoped that the furnaces may be blown in not later than March, 1922.

A technical staff and sufficient expert steel workers will be brought from Europe or America to act as executives and foremen, relying upon the country to supply unskilled labor. In course of time doubtless many of the more skilled posts will be filled by Brazilians.

Albany, N. Y.

Portland Cement Output Increases in October

There were appreciable increases in both production and shipments of portland cement in October, 1921, notwithstanding the seasonal trend. The production exceeded that of October, 1920, and according to available statistics was the largest ever recorded for a single month. The production for the first 10 months of 1921 was greater than the production during the corresponding period of 1920 and about 10.5 per cent in excess of the average for the same period during the 5 years 1917-1921.

The production of clinker, or unground cement, in October was approximately 9,891,000 bbl. Clinker production for the 10 months amounted to approximately 82,419,000 bbl.

The statistics shown in the following table, prepared under the direction of Ernest F. Burchard, of the United States Geological Survey, are based mainly on reports from producers of portland cement and in part on estimates.

PORTLAND CEMENT STATISTICS FOR FIRST 10 MONTHS, 1921

Month	Production, Bbl.	Shipments, Bbl.	Stocks at End of Month, Bbl.
January.....	4,098,000	2,539,000	10,300,000
February.....	4,379,000	3,331,000	11,400,000
March.....	6,763,000	6,221,000	12,000,000
First quarter.....	15,240,000	12,091,000	
April.....	8,651,000	7,919,000	12,600,000
May.....	9,281,000	9,488,000	12,450,000
June.....	9,296,000	10,577,000	11,150,000
Second quarter.....	27,228,000	27,984,000	
July.....	9,568,000	10,301,000	10,414,000

September.....	10,027,000	11,329,000	6,953,000
Third quarter.....	29,839,000	33,970,000	
October.....	10,506,000	12,114,000	5,348,000
First 10 months.....	82,813,000	86,150,000	

Meters for Ammonia Liquors

BY A. THAU

Superintendent of the Oxelösund Coke Works, Sweden

IN CONNECTION with an earlier article describing the operation of column stills for ammonia and benzene,¹ the metering of the liquors before entering the stills was urged. It was also pointed out that the usual water meters of the wheel or propeller type are not always adapted for measuring ammonia liquor or oil. The positive acting piston-type meter was therefore recommended, and since the author has received a number of inquiries as to the principle of these meters and the details of their construction, it is believed that their description may be received with a measure of interest.

The metering of clean and neutral liquids to a high degree of accuracy does not present any difficulties, but when it comes to measuring liquids fed into stills, such as ammonia liquor or benzolized oil, special precautions must be taken to insure a continuous feed and at the same time an accurate record of the volumes which have passed through the meter and still. Both the ammonia liquor and benzolized oil react alkaline, and furthermore they are seldom free from solid substances. The alkaline reaction makes it impossible to use copper, brass, bronze, nickel or aluminum for the internal parts of the meters coming in contact with the liquid, and in the presence of benzene, vulcanite is also attacked and is therefore objectionable. For these reasons the usual water meters are impracticable for this purpose and they possess the additional disadvantage that they are easily obstructed by pieces of naphthalene or anthracene carried forward or held in suspension by the liquids. Filtering vessels to retain the solids before entering the meter soon become obstructed and check the flow.

Other means of measuring the liquids are resorted to in most cases. Weir meters which record the volume of the liquor or oil in accordance with the height of the

FIG. 1. A TILTING DEVICE FOR METERING LIQUIDS

liquid passing over the weir are often used. As reliable as they may be for clean water or oil, any solid substances obstructing even a small area of the weir temporarily affect the accuracy of the measurements.

Another type of flow meter consists of two vessels which are filled and emptied alternately and by recording the number of fillings give an indication of the volume passed. For example, tilting vessels, such as are shown in Fig. 1, are frequently applied. This

tilting vessel is divided by a central partition directly above the pivoted shaft on which the device is supported. When one half is filled, it overbalances and empties itself, and the other half comes into the filling position under the feed pipe. One end of the shaft is connected to a counting mechanism indicating or, by a supplementary electrical arrangement, recording the number of fillings over a given time. As simple as this arrangement looks, its degree of accuracy is not very great and there is no immediate indication in case the device gets out of order. If the pivots become worn or unhooked,

FIG. 2. VERTICAL SECTION AND ELEVATION OF PISTON-TYPE METER

the liquor will simply pass forward without the vessel tilting and the volume is then not indicated on the index. Even when the device is working properly a certain spill during tilting must be taken into consideration. This is naturally omitted on the records and is difficult to estimate, as its proportion varies with the amount of feed. All these measuring devices have also the great disadvantage that they must be placed at such a height that their outlet provides sufficient head for feeding the stills; consequently they are usually erected in the most inaccessible and unobservable places.

One type of meter which can be placed into the feed pipe of the still near the floor level is the flow meter previously described in these columns,² and while it is quite reliable, it only gives indications of the volume passing through the feed pipe at the time of observation. It does not add, as is expected of a meter from which a continuous record is obtained.

The disadvantages of these measuring devices are largely overcome by the use of the positive acting piston-type meter. This is a very reliable apparatus, of simple design, and its indications are very accurate. The meter is shown in vertical section and in elevation in Fig. 2. In its principle it resembles very much that of a steam engine, where the cylinder serves as a measure and the piston rod acts upon a valve causing the piston to reciprocate, at the same time acting upon the mechanism of a dial index to record the amount of liquid which has passed through the meter.

In Fig. 2 C represents a vertical cylinder which holds

¹Thau, A., "Ammonia and Benzene Column Stills," CHEM. & MET. ENG., vol. 23, No. 25, pp. 1203-7, Dec. 22, 1920.

²CHEM. & MET. ENG., vol. 23, No. 25, p. 1206, Dec. 22, 1920.

the piston *P* with rod *R*. The cylinder *C* is machined inside and the piston is provided with three cast-iron piston rings to give it an absolutely tight fit. The bottom and the top of the cylinder are each provided with port holes, the former being connected by the passage *B* and the latter by *D* to a common four-way valve *V* on top. This valve separates the inlet branch *A* and outlet branch *O*. The top of the piston rod *R* carries a double rack *X* which is slotted through in its center to enable the shaft of the valve *V* to pass through it without hindering the vertical movement of the rack. On its upper end the rack engages with gear wheels, by means of which it turns the toothed wheel *N*. In revolving, the wheel raises the balance weight *G* fixed to a lever and lifts it up so high that it overbalances and drops down to its opposite side, its fall being terminated by a soft buffer arranged on each side. A projecting edge *E* on the weight *G* comes in contact with lever *T*, which operates valve cone *V*.

The liquor enters at *A* and is conducted by the corresponding position of the valve *V* to the passage *B*, thus entering the cylinder *C* from the bottom and lifting the piston *P* to its highest position. At the same time the liquor filling the cylinder space above the piston is forced by the raising of the latter through the passage *D* and the corresponding ports of the valve *V* to the outlet branch *O*. When the piston has reached its highest position, the rod *R* and rack *X* cause the balance weight *G* to overturn, thereby giving the valve cone *V* half a turn, so that the flow of the liquid through the cylinder is reversed. The liquor enters now through the passage *D* and presses the piston downward, forcing the liquor underneath the piston to be expelled through the passage *B* and to be conducted through the valve *V* to the outlet *O*. The overturning of the weight *G* and the reversing of the valve, when the piston reaches its highest or lowest position respectively, is effected so rapidly that the continuous flow of the liquid is in no way interrupted. The strokes of the piston are transmitted to the meter-index *Z* by means of gear wheels which are held by the bracket *R* indicated in liters or gallons. The meter is provided either with the ordinary gas meter index with five dials and pointers or with a row of jumping figures like those on meters for measuring electric current.

ADVANTAGES OF THIS METER

The indications of the meter are accurate to 1 per cent and are guaranteed not to vary more than $1\frac{1}{2}$ per cent, a margin which must be considered very close for the purpose they serve. For use in connection with ammonia or benzene plants, the interior parts of these meters coming in contact with the liquids are made entirely of iron, while in the case of measuring fresh water some parts, such as the piston, piston rod, top gland and valve cone, can be made of brass or bronze.

A number of these meters are in use in England and on the European Continent for varying purposes, in the majority of cases as feed-water meters for boilers, and offer the advantage that they can be placed into the pressure feed pipe between feed pump and boiler. For this purpose the meters are tested to withstand a pressure of 300 to 375 lb. per sq.in.

The meters used in connection with boilers are connected into the feed pipe at a convenient place on the pressure side of the pump. In the case of ammonia or benzene stills, they are connected to the feed pipe between the high level tank and the still and are placed

at a convenient and easily accessible position on the ground floor. They require very little pressure for acting, 70-in. water gage being sufficient to use them. Much higher pressures are required for feeding the stills.

It may be further mentioned that with the exception of the piston all movable parts are open, can be observed during working and are readily accessible. No gears are exposed to the liquid to be metered and the pressure resistance of the meter is scarcely noticeable. The temperature of the liquid passing the meter does not affect its working and the four-way valve is so constructed that it can be tightened while the meter is in operation. The speed of the liquid passing through the meter is comparatively slow and the piston makes two to ten double strokes per minute. By these means the wear and tear of such meters is very small and their upkeep very slight. Obstructions do not generally interfere and therefore filtering arrangements are not required.

"Squaring a Circle"

BY C. T. PATTERSON

The accompanying photograph gives one way to solve the classical problem, "How to square a circle."

It is a sulphur print of a shaft which failed after a very short life. The section was polished and laid on a film saturated with 4 per cent H_2SO_4 . The film was then fixed, washed and dried in the usual way, and it now

"A SQUARED CIRCLE"

serves to make any number of exact duplicates of a single sulphur print.

Sulphur contents of the center and outside are respectively 0.11 and 0.05 per cent.

The shape of the segregate may be explained by the idea that the steel, cast in a square mold, built up a segregate forming a roughly cylindrical or conical volume in the center. When the square ingot was rolled to a $3\frac{1}{2}$ -in. round bar, the circular segregate was squared. Part of the bar was then turned down to $2\frac{1}{2}$ -in. for a piece of shafting, and the result was as shown in the illustration.

Solvay, N. Y.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Alum and Aluminum Sulphate From Alunite.—The invention consists in the preparation of alum and aluminum sulphate from alunite without the use of sulphuric acid. The coarsely crushed ore is roasted, preferably in the absence of material quantities of air and in a furnace in which the ore is passed down a series of hearths, the bottom one or more of which are heated to 700-900-deg. C. The sulphur dioxide, sulphur trioxide and oxygen which are evolved thus come in contact with the descending alunite and the iron oxide contained therein, acting as a catalyst, causes the sulphur dioxide and oxygen to recombine. The gaseous products from the furnace pass over some ground previously calcined alunite in a drum or chamber into which sufficient water is sprayed to convert the sulphur trioxide into sulphuric acid, whereupon a substance is produced from which alum and aluminum sulphate are obtained by lixiviation. The alum and aluminum sulphate may be separated by fractional crystallization or sufficient potassium sulphate, which may be obtained by extracting another portion of calcined ore with water, is added to combine with the free aluminum sulphate to form alum. The residue of calcined alunite that cannot be employed as above described may be used as a potash fertilizer or as a source of alumina and potash. (Br. Pat. 167,555. A. Matheson, London. Oct. 5, 1921.)

Utilizing Waste Rubber.—Rubber and textile material are recovered from waste rubber fabric by treating it, without reducing it to a state of fine division, with a solvent, the material and solvent being heated and kneaded or agitated under pressure, the temperature not rising above 120 deg. C. For this purpose the fabric is introduced with solvent into a rotary perforated cage 3 in an airtight steam-jacketed chamber 1. Stirring blades 7 are provided which do not rotate with the cage, but can be raised out of the liquid as shown. Ribs, etc., on the interior of the cage may assist in the agitation. The cage 3 is rotated in opposite

directions alternately by gearing comprising fast and loose pulleys 18, 19, 20, 21 and straight and crossed belts 22, 23. When the operation is completed, the solution is run off through a cock 30 into a vessel 31, and the cage rotated rapidly to expel the remainder of the solution. The fabric is then washed with a fresh charge of solvent which is similarly expelled. Air or an inert gas is then circulated through a heater 39, the chamber 1 and a condenser 35 to

remove the last traces of solvent, which are collected in a vessel 26. The solution and the solvent which has been used for washing may be collected separately. (Br. Pat. 167,667. F. Waitz, Bremen, Germany. Oct. 5, 1921.)

Dialkylaminoalkyl Compounds.—Dialkylaminoalkyl compounds are prepared by interaction of halogenalkyldialkylamines and the alkali salts of compounds of the type $R.CO.CHR_1X$, where R, R_1 are hydrogen or any radicals and X is an electro-negative group such as $-COOC_2H_5$, $-CO.CH_3$, $-CO.C_6H_5$, $-CN$; for example acetoacetic ester, cyanacetic ester, malonic ester, acetonedicarboxylic acid ester, camphorcarboxylic acid ester, succinyl-succinic acid ester, acetylacetone; alternatively, the compounds may be prepared from halogenalkyl derivatives of bodies of the above type, such as bromethylacetate or bromethylacetoacetic ester and dialkylamines. According to examples the following compounds are prepared: α -diethylaminoethylacetoacetic ester from sodioacetoacetic ester and chlor- or bromethyldiethylamine, or from α -bromethylacetoacetic ester and diethylamine; α -diethylaminoethylacetoacetic methyl ester; α -dimethylaminoethylacetoacetic ethyl ester; diethylaminobutylacetoacetic ethyl ester; diethylaminoethylmalonic diethyl ester; diethylaminoethylcyanacetic ester; bis-diethylaminoethyl-diketohexamethylenedicarboxylic acid diethyl ester from sodio-succinylsuccinic acid ethyl ester and chlorethyldiethylamine; diethylaminoethylacetonedicarboxylic acid diethyl ester; diethylaminoethylcamphorcarboxylic acid methyl ester; diethylaminoethylacetylacetone. Chlorethyldiethylamine is made by adding diethylaminoethanol to thionyl chloride in chloroform solution and decomposing the hydrochloride with potassium carbonate. Bromethyldiethylamine is made by boiling diethylaminoethanol hydrobromide with hydrobromic acid of 48 per cent strength. Chlorbutyldiethylamine

is made by reducing the corresponding diethylaminobutanone to the alcohol and treating the latter with thionyl chloride. The dichlorethylate of diethylpiperazine is obtained as a byproduct in the preparation of α -diethylaminoethylacetoacetic ester. (Br. Pat. 167,781; not yet accepted. Farbwerke vorm. Meister Lucius and Brüning Höchst-on-Main, Germany. Oct. 5, 1921.)

Tanning.—Hides, preferably after being subjected to a high vacuum, are tanned under pressure by liquor from which all air has been removed. Treatment with thin glue or gelatine may follow. The depilated and preferably dried hides are suspended in an autoclave and subjected for 30 to 60 minutes to a high vacuum, a strong tanning liquor from which all air has been removed by passage through a vacuum machine, etc., being then pumped in, preferably under a pressure of from 20 to 40 lb. per sq.in. After the tanning liquor has been run off, the hides are washed, and a solution of thin glue or gelatine is forced into the pores by alternate high vacuum and high pressure. The hides may be again washed and are dried in vacuo, small quantities of hot air being admitted, preferably through a red-hot-pipe. (Br. Pat. 167,785. A. Mauvers, London. Oct. 5, 1921.)

Separating Organic Substances by Distillation. The separation of the constituents of mixtures such as crude resorcinol, crude anthracene cake, crude anthraquinone, etc., is effected by distilling the substance with a mineral oil, such as kerosene, fuel oil, etc., containing fractions which boil within wide limits. The constituents of the mixture distill over with the oil at different stages and are collected separately. Alternatively, a mineral oil fraction having a boiling point above that of any of the constituents of the mixture to be separated is used. The mixture is heated and at various stages in the rise of temperature steam is passed through the mixture to carry off the constituents separately in the order of their volatility. In treating crude anthracene cake carbazol passes over first, then anthracene, and finally phenanthrene. (Br. Pat. 168,108. Berk & Co., Ltd., and J. J. Hood, London. Oct. 12, 1921.)

Ammonium Sulphides.—In preparing ammonium sulphide or polysulphide, ammoniacal liquor is heated under such conditions of temperature and pressure as to expel carbon dioxide but not sulphuretted hydrogen. The liquor is then distilled to obtain ammonia solution containing ammonium sulphide, which is treated with sulphuretted hydrogen prepared, for example, from iron sulphide and sulphuric acid, to yield ammonium sulphide or, if sulphur be added, ammonium polysulphide. The ammonium liquor is treated in an apparatus comprising two columns *a*, *b*. The liquor enters the column *a* by inlet *c* and is treated by the vapors from the column *b* entering by pipe *d*. The liquor passes from column *a* through a cooler *f* and then to the top of the column *b*, in which it is treated with steam from a pipe *i*. The liquor passes from the base of the column to an ammonia still. The vapors from the column *a* pass to a column *l*, in which they are washed with water. The unabsorbed gases escape by a pipe *n* and the wash water passes by a pipe *o* into the liquor leaving the column *a*. The temperature at the steam inlet *i* may be kept at 98 deg. C., and the pressure at 16 lb. per sq.in. absolute. Higher temperatures and higher pressures or lower temperatures and lower pressures may be used. (Br. Pat. 167,540. South Metropolitan Gas Co. and P. Parish, London. Oct. 5, 1921.)

of descriptions of sintering machines and the production of liquid SO_2 .

The latter criticism—that is, space used on unimportant points—might also be applied to the description of the supplying of niter to chambers by the oxidation of ammonia, especially since, by the authors' own statement, only one such installation exists in this country.

In the description of the contact method, the effort to cover the whole subject in a very limited space is particularly noticeable and has resulted in a series of more or less unrelated statements rather than a connected discussion. Some of these statements are very good; others are of little importance.

It is assumed by the reviewer that a misprint is responsible in Fig. 80, page 241, for the word "converters" under a picture showing coke boxes and mineral wool filters.

The tables in the back of the book are good.

While this book has an undoubted value in the literature of acid making in that it is the first effort of independent authors to cover the American field, one finishes reading it with a feeling that the subject might have been better handled by the expenditure of a little more effort and by more attention to literary style.

THOMAS R. HARNEY.

CHEMICAL REACTIONS AND THEIR EQUATIONS.

A Guide and Reference Book for Students of Chemistry.

By I. W. D. Hackh, professor of biochemistry, College of Physicians and Surgeons of San Francisco. Philadelphia: P. Blakiston, Son & Co. Price, \$1.25.

This is one of the most convenient and helpful little books we have come across in a long time. It is small enough to carry in a side pocket, contains only 138 pages, and does not profess to cover any more ground than its title indicates. The author found so many graduate students who were unable to balance an incomplete ionic equation that involved oxidation or reduction that he wrote the book for them. It confines itself merely to a consideration of purely chemical equations from a technical and arithmetical standpoint. There are six chapters, treating respectively of: Symbols, Formulas, Equations Involving No Oxidation or Reduction, Equations Involving Oxidation and Reduction, Reactions and Their Control, and Types of Chemical Reactions and Equations. After each chapter a group of carefully chosen questions reviews the subject comprehensively. It concludes with an appendix which adds a Key to Nomenclature, With a List of Radicals, Ions and Valence Numbers, Displacement Series of the Elements, Periodic System and Classification of Elements, Solubility Table of Compounds, Preparation of Salts, Key to Equations, and an Index and Glossary of Chemical Terms.

A vast amount of useful information is condensed into a small space, and a large number of facts are conveniently arranged. It is bound to be not only a very present help in the study of chemistry, but also a handy book for the forgetful chemist.

ELLWOOD HENDRICK.

TECHNICAL METHODS OF ANALYSIS, as employed in the Laboratories of Arthur D. Little, Inc. Edited by Roger Castle Griffin, Director of Analytical Department, Arthur D. Little, Inc. International Chemical Series. 666 pp., 5½ x 8, 29 illustrations. Price, \$6.

The author is to be commended for the comprehensive and concise manner in which he has covered a very wide range of quantitative analytical methods. This book should be very helpful to those interested in general analytical work. The main body of the text is supplemented by a bibliography which refers to many standard treatises on special subjects. A chapter on "The Analysis of Textile Fibers" contains much valuable information not commonly found in other standard works on quantitative analysis. There are few noticeable omissions to be pointed out, except possibly the failure to mention an additional method for the determination of cotton in asbestos-cotton twine. Cotton is readily and fairly accurately determined by combustion in a stream of oxygen, weighing the resultant carbon dioxide and calculating to cellulose. On the whole the book possesses great utilitarian value in the hands of the analytical chemist.

A. F. SHUPP.

Book Reviews

AMERICAN SULPHURIC ACID PRACTICE. By Philip De Wolf and E. L. Larison. Pp. 270; 85 illustrations, New York: McGraw-Hill Book Co., Inc., 1921. Price, \$3.50.

One feels that the authors of this little book have perhaps attempted too much in an effort to cover so general a subject as "American Sulphuric Acid Practice" in such limited space, and this is, perhaps, the cause of the somewhat disconnected and more or less unrelated style employed. To lack of space may be due also the authors' failure to give supporting evidence for statements which are sometimes at variance with opinions generally held among acid men.

Most noticeable of these unsupported statements is the remark on page 6, where, in a discussion of the relative merits of "contact" and "chamber" processes, the authors state: "Supervision, regulation and yield are all better on a contact plant, while depreciation and maintenance are less." This is so entirely contrary to the reviewer's experience that he feels that perhaps an error has been made in printing and that for "contact" one should read "chamber."

The part of the book devoted to the chamber process is, on the whole, more complete and better written than that devoted to the contact method. It is somewhat surprising, however, to find that in a book on American sulphuric acid practice no mention is made of Pratt chambers, as it is probable that more chamber acid is made in the United States in Pratt sets than in any other special type of chamber.

While the descriptions of various apparatus and methods for the production of SO_2 are interesting, it would seem that a little more detailed information on actual acid manufacture might well have been incorporated at the expense

Current Events

in the Chemical and Metallurgical Industries

More Plants Increasing Operations

Glass. The Thatcher Glass Co., Dunkirk, N. Y., has resumed operations at its local bottle-manufacturing plant under a 24-hour working schedule, following a two months' shut down. About 150 men will be employed. The company has made improvements at the works to an amount of about \$100,000.

The Lippincott Glass Co. will soon place a 10-pot furnace in operation at its Alexandria, Ind., works, giving employment to about 200 men. Repairs and improvements preparatory to resumption are now being made. The local plant will commence the manufacture of glass tumblers in the near future.

Ceramic. The Hall China Co., East Liverpool, Ohio, has resumed operations at its No. 2 plant, following a period of curtailment. There is now only one semi-porcelain manufacturing plant idle in this district.

The Crouse Clay Products Co., Akron, Ohio, manufacturer of brick, has increased operations to normal at its plant.

The Cincinnati Clay Products Co., Cincinnati, Ohio, manufacturer of brick, has increased production at its plant, giving employment to a considerably increased working force as compared with this time last year.

The Atlantic Terra Cotta Co. and the Federal Terra Cotta Co., with plants at Perth Amboy, N. J., are increasing the working forces in the different departments of their factories.

Paper. The Universal Paper Bag Mill and the Union Paper Mills, both of New Hope, Pa., have adopted a full-time operating schedule at their plants.

Chemical. The du Pont Chemical Co., Pennsgrove, N. J., has added about 1,000 employees at its Deepwater Point plant, bringing the working force up to a total of 2,500 operatives. Further increase in the number employed is expected at an early date.

Rubber. The Rubber Products Co., Barberton, Ohio, has adopted a night working schedule at its plant.

Oil. The Tidewater Oil Co., Bayonne, N. J., has resumed operations at its refineries, following a strike of operatives. A settlement with the men was arranged on a basis of 12 per cent wage reduction.

The New York Petroleum Corporation, El Dorado, Ark., has commenced production at its new local refinery under full capacity, totaling about 2,000 bbl. of oil per day.

Glue. The Perkins Glue Co., Lansdale, Pa., has placed an overtime working schedule in force, including night and Sunday operations.

Soap. The Procter & Gamble Co., Cincinnati, Ohio, is maintaining capacity production at its local plant.

Leather. The American Hide & Leather Co., Sheboygan, Wis., has increased operations at its local tannery to close to normal production.

The Badger State Tannery, Sheboygan, Wis., is giving employment to about 225 operatives, who are turning out the same ratio of leather as did 400 employees prior to the fire at this tannery in January, 1920, due to improved machinery and better working conditions, with modern buildings. Production is near to normal.

Iron and Steel. The Carnegie Steel Co., Youngstown, Ohio, has blown in its fifth blast furnace at its Ohio works, bringing production up to over one-third of normal.

The Trumbull Steel Co., Youngstown, Ohio, has placed eight of twelve mills in operation at its Liberty plant, which has been idle for eight months past.

The Portage Foundry Co., Barberton, Ohio, has increased production to more than 60 per cent of normal.

The Berks Foundry & Manufacturing Co., Hamburg, Pa., has adopted a full-time operating schedule at its plant, with increased force of molders.

War Minerals Relief Act Modified

Without the necessity of a roll call, the House of Representatives on Nov. 22 agreed to a Senate amendment to the war minerals relief bill which removed the necessity of re-appropriating the remainder of the war minerals fund for the payment of additional awards. The bill was signed by the President on the following day, thus becoming a law. This measure amends the original act as follows:

Add to the first paragraph of Section 5 the following proviso: "Provided, That all claimants who in response to any personal, written or published request, demand, solicitation or appeal from any of the government agencies mentioned in said act, in good faith expended money in producing or preparing to produce any of the ores or minerals named therein and have heretofore mailed or filed their claims or notice in writing thereof within the time and in the manner prescribed by said act, if the proof in support of said claim clearly shows them to be based upon action taken in response to such request, demand, solicitation or appeal, shall be reimbursed such net losses as they may have incurred and are in justice and equity entitled to from the appropriation in said act.

"If, in claims passed upon under said act, awards have been denied or made on rulings contrary to the provision of this amendment, or through miscalculation, the Secretary of the Interior may award proper amounts or additional amounts."

The measure includes an amendment proposed by Representative Anderson, of Minnesota, which broadens the language so as to allow claims when a written notice of their existence was filed prior to the expiration of the time limit. This amendment is understood to have been intended to admit two Minnesota claims totaling about \$750,000.

Asbestos Industry Shows Marked Improvement

Reports from leading companies in the asbestos products industry show a marked improvement in the business in this line, and increasing volume of orders. The Johns-Manville Co. reports record sales in October as compared with other months of this year, and more asbestos shingles were sold during that month than at any other time in 1921. The Keasbey & Mattison Co. reports a 100 per cent increase in business during this same month, with marked prospect for further advancement. The Keystone Asbestos Co. states that there has been considerable improvement in the orders placed for building and insulation asbestos, while the Ehret Magnesia Mfg. Co. reports 35 per cent increase in October sales as compared with the preceding month.

Increased Appropriation for C.W.S. Approved

The President and the director of the budget have approved a request for an appropriation of \$1,500,000 for the Chemical Warfare Service during the next fiscal year. This is an increase of \$150,000 over the amount appropriated for the current fiscal year. Among the items making up the total asked for next year's work are: Salaries and wages, \$1,007,444; materials and equipment for research and experimentation, \$143,023; chemical supplies, \$65,000; offense appliances and supplies, \$40,000; gas mask materials, \$21,000. These estimates of expenditure were submitted to Congress by the President on Dec. 5.

Employment Increases in Chemical Industry

There was an increase of 1.3 per cent in employment in chemical industries during November, according to a report issued Dec. 5 by the United States Employment Service. There was an increase of 0.46 per cent in employment throughout the country during November.

A Tribute to Canadian Business Papers

Ontario's Lieutenant-Governor, Colonel Henry Cockshutt, president of the Cockshutt Plough Co., Director of the Bank of Montreal, etc., himself an outstanding success as a business man and financier, paid an understanding tribute to the business papers of Canada when, speaking at a luncheon in connection with the annual meeting of the Canadian National Newspapers and Periodicals Association at the King Edward Hotel, Toronto, on Thursday, Nov. 10, he said:

"I am especially glad to be with you today because I believe that the influence of the business press will be one of the most important factors in re-establishing business conditions in Canada on a safe and sane basis. I make a distinction between the business newspapers and the daily press, because I believe that your papers—the business newspapers of Canada—exert a greater influence than the daily press because of the greater confidence your readers have in them. People read the daily newspapers to satisfy their desire for excitement or interest or entertainment. But this is not the case with the business newspaper. Business men need the service of these papers in the conduct of their everyday business life.

"You should be very careful that everything that appears in your columns bears the imprint of the truth. You must be sure that the news you give is correct beyond question, because there are thousands of your readers ready to set their business course by the news and advice you give them.

"In these days when there is disorganization, dissention, disruption in all walks—business, politics and religion, there is a great place for the business paper to bring out more complete information, to assist in making us all realize we must work for a common cause—the upbuilding of our country. The business men of this country need your assistance. They are looking to you for information and advice, and are expecting it. On your shoulders therefore, perhaps more than on the shoulders of any other single agency, rests the obligation to meet the needs of these trying days, with a sane and sound presentation of the case as it exists at the present time, a presentation free from private bias or the desire to serve a popular demand."

Fundamental Research Program for Cotton Seed and Cottonseed Products

Pursuant to the memorials adopted at the last meeting of the American Oil Chemists' Society and the Interstate Cottonseed Crushers' Association in Chicago in May of this year, a joint committee of the two organizations met with the officials of the U.S. Department of Agriculture of Washington for the purpose of acquainting them with the needs of the industry in certain lines of research, endeavoring to obtain their aid in having studies along these lines actively prosecuted and establish more intimate relations between the Agricultural Department and the cottonseed oil industry. To this end the committee recommended research along well defined lines incorporated in the following brief:

In the interest of the farmer producer, the converter of cotton seed into marketable food and the consumer of those products, we the basic research committee of the Interstate Cottonseed Crushers' Association and of the American Oil Chemists' Society, appointed at the suggestion of Secretary Wallace to advise and co-operate with the interbureau committee on oils and fats in the Department of Agriculture, respectfully submit to the department the following tentative program of research to be conducted in co-ordination by the various bureaus of the department having facilities and authority for such work.

(1) To develop varieties of cotton seed that will yield fiber of the maximum value and seed containing the maximum percentage of oil and also to determine the effects of cultural conditions.

(2) Isolation and identification of all constituents of crude cottonseed oil with special reference to effect on refining loss and quality. This would serve as a foundation for improvement in refining methods which will result in a larger yield of refined oil from the raw material and will also serve as the basis for a correct valuation of the crude oil.

(3) Continuance of work on rancidity with special reference to the nature and constitution of the products formed and their physiological effects. This will serve as the basis for determining why rancid fats are objectionable or harmful. It will also lead to a knowledge of methods for the prevention and removal of rancidity from oils and fats.

(4) Isolation and identification of constituents of cottonseed meal with special reference to feeding values. This will lead to the investigation of the so-called toxicity of cottonseed meal and establish definite information which will clear up any existing uncertainty regarding its use as feedstuff for all classes of farm animals. It will also furnish facts bearing upon the use of cottonseed meal for human use.

(5) The prompt publication from time to time by the department of results of its research in oils, fats and other products of the oil milling industry, and the revision or re-editing of all present bulletins, in cases of re-publication, with a view to correcting inaccurate data and conclusions based thereon. (Note. Reference is made here to Farmers Bulletin 36 and to Farmers Bulletin 1,179 and all other literature issued by the department in which the conclusions have been reached and data published that are not justified by present day information.)

(6) We ask that data of researches regardless of conclusions be made freely accessible to interested parties upon request.

This committee tenders its services in carrying out the above program and asks an opportunity to discuss with the department, from time to time, these research problems, their progress and contemplated publication. The committee offers to obtain and place at the disposal of the Agricultural Department all possible available data from the industry pertaining to its work.

On Oct. 4 the committee met with the officials in Washington and considered the matter from the standpoints of the various bureaus affected, with the result that plans are now under way for actively prosecuting these studies. In conjunction with this governmental research the committee on co-operation in research of the American Oil Chemists' Society has obtained from representatives of the industry, comprising chemists, technologists, engineers and producers, a list of problems which it is transmitting to the universities and experiment stations as a guide to them in planning such research along these lines as they may be in a position to prosecute.

A.A.A.S. to Meet in Toronto

The seventy-fourth meeting of the American Association for the Advancement of Science will be held at Toronto, Canada, Dec. 26 to 31, by invitation of the University of Toronto and of the Royal Canadian Institute. Meetings of interest to chemists are, besides the meetings of Section C (Chemistry) itself, a joint meeting with the Canadian Institute of Chemistry and the Toronto Section of the Society of Chemical Industry, at which Prof. S. W. Parr, retiring vice-president for Section C, will give his address on "The Carbonization of Coal"; a joint meeting with the Plant Physiology Section of the Botanical Society of America, devoted to biochemistry and chemical aspects of plant and animal physiology; and a symposium on the quantum theory, jointly with the American Mathematical Society and the American Physical Society.

Two Pottery Expositions Being Arranged

East Liverpool, Ohio, pottery manufacturers are arranging plans for two expositions early in 1922. The first will be held at Pittsburgh, Pa., in January, and upon the closing of the display it will be removed to Chicago, to be on exhibition there in February.

Brunner Mond Dividend

The directors of Brunner Mond & Co., Ltd., chemical manufacturers, announce an interim dividend of 2½ per cent, less tax. For the corresponding period of the previous year the distribution was at the rate of 10 per cent, less tax.

Successful Flight With Helium

The first practical demonstration of the use of helium for aircraft was made at Hampton Roads, Va., on Dec. 1, when the navy non-rigid airship C-7, filled with the gas, made two successful flights.

Philadelphia Chemical Club Celebrates Anniversary

The Philadelphia (Pa.) Chemical Club, composed of chemical manufacturers and others in the local trade, celebrated the first anniversary of its organization with a dinner at the City Club on Nov. 19. Reports made at the meeting showed a large and growing increase in the membership. Major Maurice Mercadier, of France, gave an interesting talk on the subject of "Exchange," and A. J. Morse spoke on the topic of the "American Melting Pot."

Merger Proposed to Establish Steel Industry in West

A plan has been proposed for the utilization of the enormous deposits of coking-coal and iron ore in Utah in establishing a steel industry to supply the Pacific Coast trade which now has to depend upon the Eastern manufacturers for finished products. The plan takes the form of a \$20,000,000 merger comprising a number of companies that control coal mines and iron ore deposits in Utah and two others that own and operate steel plants in California. Under the combination, iron ore from the deposits in the Iron Springs district of Iron County, Utah, limestone from the extensive quarries near Salt Lake City, and coke from a proposed byproduct coke plant would be smelted in a 500-ton blast furnace to be located near Utah Lake, 25 miles south of Salt Lake City. The pig iron would be shipped to the plants of the Columbia Iron & Steel Co., at Pittsburg, Cal., and at Portland, Ore., and the Southern California Steel Co.'s plant near Los Angeles. These plants would be expanded.

Patent Office Continues to Degenerate

When Commissioner Newton was in charge of the Patent Office, in July, 1919, he testified before a committee of Congress to the effect that the situation in his bureau was deplorable and that it was in a worse condition at that time than at any other time since he had been in the service. His service began in 1891. The present Commissioner of Patents, in his report to Congress, points out that the degeneration has continued steadily since the testimony of Commissioner Newton. Between July, 1919, and June 30, 1921, the Patent Office lost 163 of its examiners. "These men," says the Commissioner in his report, "were scientifically trained and also members of the bar. They have been replaced by inexperienced men, fresh from college, without any knowledge of patent law and without legal training." Continuing, the report says:

"During the time the Patent Office has been losing the 163 men aforesaid, the number of applications received in this office has increased by leaps and bounds. The number of applications for patents has increased 34 per cent during the period under discussion, while the trade-mark applications increased 85½ per cent. In July, 1919, when Commissioner Newton testified, there were 18,000 patent applications awaiting action. There are now about 50,000 applications awaiting examination. It is further shown that a number of divisions are over 11 months behind in their work, and to illustrate the large turnover in the personnel, there is cited one of the chemical divisions where five out of the nine examiners have been appointed in the last few months. At the close of the fiscal year, one of these had been in the office only 1 week, another 3 weeks, another 7 weeks and another 2 months. One out of every four examiners has resigned in 16 months and more than one-half have resigned in 32 months. Relief is, therefore, imperative.

"It is shown that there are many industries which can not enter into development work on account of the doubtful status of their applications for patents. A bill is now pending in the House H.R. 7077, which is designed as an emergency measure to help relieve the situation.

"Reference is made to the entrance salaries of the assistant examiners, who are a highly educated and picked corps of scientific men, who receive the same initial salary as clerks who perform routine duties in other branches of the government service. Note is made of the inadequacy of the salaries paid to these technical men as compared to their qualifications and the requirements of their position, showing the necessity of correcting the disparity of conditions.

"The receipts of money for the fiscal year just closed increased from \$2,615,697.33 of the previous fiscal year to \$2,712,119.69, or almost \$100,000. A net surplus of \$284,342.93 was earned, and if the bonus be subtracted therefrom, the surplus amounted to \$71,745.73, making the total net surplus to date—that is, the excess of receipts over expenditures during the history of the Patent Office—\$8,376,769.29.

"Emphasis is laid upon the figures given and the conditions cited to show that the volume of business presented to the Patent Office is altogether too large for the present personnel to perform properly."

Alcohol Export Situation

So as to be able to take advantage of a demand for American alcohol in Europe, the producers of industrial alcohol in the United States are urging that this traffic be permitted to move without undue interference from the Bureau of Internal Revenue. Captain James P. McGovern, representing all the alcohol producers in the United States, has submitted the following statement to the Commissioner of Internal Revenue and to the Federal Prohibition Commissioner:

"A condition has arisen in Europe whereby, because of lack of raw material necessary for the manufacture of alcohol, there is a demand for the purchase of alcohol manufactured in this country to be exported to sundry European countries for legitimate industrial uses there.

"The disturbed conditions in Europe have curtailed the raw material, such as molasses, the result of the beet sugar crops in various European countries, and of grains and potatoes, which are used in other countries as raw material for alcohol. The great and almost universal drought in Europe during the last summer will further tend to a restriction of raw material for the manufacture of alcohol in those countries. The result is that there is and will be a real necessity for alcohol in Europe for the arts and industries and a demand for the exportation of alcohol produced in the United States. This foreign trade, which is legitimate, should not have an embargo placed thereon simply because there have been isolated cases of attempts by bootleggers and irresponsible parties to feign the exportation for the purpose of surreptitiously bringing it back into illegal consumption in the United States. The mere fact that our governmental authorities are aware of this and have been able in some cases to prevent it shows that under proper regulation and vigilance and honest administration of existing laws such shipments can easily be controlled. Under no circumstances should the producers of alcohol in this country be deprived of their legitimate and lawful right of exporting their commodity to foreign countries, particularly in the case of alcohol, where the foreign market for American alcohol will cease to exist just as soon as European raw material is available for the production of alcohol there. This is an opportunity for American producers to sell in the foreign market and they should not be deprived thereof, particularly as this is an opportunity which will only come once in a lifetime.

"A proper co-operation of the various departments of the Treasury—namely, the Internal Revenue and Customs Service—even under present existing laws and regulations, will certainly safeguard the enforcement of the prohibition laws in this country. The producers of alcohol in the United States are desirous of co-operating with the government along these lines and under any reasonable and practical regulations, but the attempt to establish regulations which are now unreasonable and unnecessary will prevent the foreign trade now with these producers and any such action would not only be unwarranted and unreasonable but actually in violation of the constitutional rights of American producers."

Tax Bill Finally Approved

While the tax bill is admitted by its authors to be an imperfect measure, it does provide for a substantial reduction in the tax burden and greatly simplifies the administration of the law. The bill in its final form will require during the first fiscal year that it is in full operation the payment of about \$725,000,000 less than would have been raised had the law it supersedes remained in effect. The reduction will be greater when collections from the excess profits tax cease altogether.

The repeal of the transportation and so-called nuisance taxes means a reduction of \$326,630,266 during the fiscal year being July 1, 1921. That feature of the bill alone is held by many to justify its enactment. It was stated officially at the White House and by the chairman of the Finance Committee that the bill is intended as a temporary measure only. The great disappointment to business is that the recommendations of the Secretary of the Treasury were not carried into effect in the matter of transferring some of the higher brackets of the income tax to the estate tax title.

In its final form the bill is expected to yield \$3,216,100,000 in the fiscal year beginning July 1, 1922, and \$2,611,100,000 in the fiscal year beginning July 1, 1923. For the fiscal year of 1922 the bill is expected to raise about \$16,000,000 in excess of the government's requirements.

The Senate accepted the House rate of 12½ per cent applicable to the corporation income tax. This reduction of 2½ per cent from the rate proposed by the Senate will reduce by \$110,000,000 the annual tax burden on business. The lower rate is particularly advantageous to public utility companies and other corporations now earning small returns on their invested capital.

Exports and Imports of Chemicals in October

There was a slight upturn in chemical exports in October. Chemicals sent abroad in October were valued at \$262,214 more than the exports of September. The October exports, however, were scarcely more than one-third the value of those in October of 1920. The slump was heaviest in dyes and dyestuffs. In October, 1921, the value of all American dyes and dyestuffs shipped out of the country was \$481,927. In October of 1920 the value of these exports was \$2,251,659. The comparative figures covering the principal groups are as follows:

	1920	1921
Acids	\$479,060	\$144,860
Dyes and dyestuffs.....	2,251,659	481,927
Extracts for tanning.....	201,358	136,295
Total soda	2,430,497	514,176

The value of all chemicals exported in October was \$4,671,310. This compares with \$13,701,882 in October of 1920.

While there was a decrease in imports of chemicals on the free list, there was a decided upturn in the imports of those on the dutiable list. In the latter class the value of the exports was nearly \$700,000 greater than in September. The total imports for October, 1921, were valued at \$7,127,853, of which \$4,342,505 represent chemicals on the free list and \$2,785,348 represent those on the dutiable list. In October of 1920 the value of free-list chemicals was \$13,393,424 and dutiable-list chemicals \$5,798,615. Imports of coal-tar products during October, 1921, were valued at \$992,014. This compares with \$2,492,174 in October of 1920. The imports of gums in October of 1921 were valued at \$1,455,915. In October, 1920, the imports of gums were valued at \$4,460,316.

Independent Steel Merger Contemplated

Several independent steel companies have been considering a plan for arriving at a possible basis for consolidation. While the matter is still in a formative stage and very little definite information is obtainable, the following companies have been referred to in connection with the proposed merger: Republic Iron & Steel Co., Midvale Steel & Ordnance Co., Lackawanna Steel Co., Youngstown Sheet & Tube Co., Steel & Tube Company of America, Inland Steel Co., Brier Hill Steel Co.

Chicago Ceramists Hold Meeting

The Chicago Section of the American Ceramic Society met at the Morrison Hotel on Nov. 26 for the election of officers and semi-annual program. E. M. Bunting, of the School of Ceramics, Illinois University, presented papers prepared by himself and Dr. Washburn, on a new method of porosity measurements.

The porosity of clay specimens has previously been measured by immersion in water; the new method involves the placing of a test specimen about 1 x 1 x 4 in. in a small special glassware container, filling the complete apparatus with mercury, and permitting the mercury to run out of the bottom of the chamber into a barometer tube graduated in millimeters. Measurements of the two quantities of pressure and volumes thus procured give a measurement of porosity which is 5 to 20 per cent higher than measurement obtained by the water vacuum method. This is easily accounted for in the fact that air is more fluid than water. Accuracy of reading is greater than 0.1 per cent. The apparatus will be described in full in the November issue of the *Journal of American Ceramic Society*.

J. A. Dedouch, of the Imperishable Minature Co., gave an impromptu talk on photographic colors worked into enamels. Every whiteware plant may make a ceramic photograph as easily as the ordinary method of decorating white ware.

R. M. Onan, of the Carborundum Co., spoke on refractories as used in enameling furnaces, describing the production of a new non-oxidizable carborundum refractory, and the making of large shapes up to 12 ft. in diameter and 6 ft. high for use in a Chicago water gas plant.

The following officers were elected for the coming year: F. L. Steinhoff, of the *Brick and Clay Record*, chairman; B. T. Sweeley, of the Coomley Manufacturing Co., vice-chairman; W. Wilkinson, of the Lewis Institute, secretary-treasurer. H. E. Davis will serve as chairman of the program committee, and E. A. Brockman as chairman of the membership committee.

Drive on War Gases Expected

While the general subject of the use of gas in warfare has been taken up only in a preliminary way in the connection with the Conference on Limitation of Armament, there is reason to believe that formidable opposition to the use of gas in warfare will develop. No one has shown his hand in the open as yet, but the opponents of chemical warfare, both at home and abroad, very evidently will make a desperate effort to unseat chemical warfare from what they declare to be an undeserved position of respectability, made so by the official recognition it has received by the governments of the principal countries.

The committee which will consider chemical warfare in connection with the studies being made for the delegates to the conference is as follows: Dr. Edgar F. Smith, chairman; General Amos A. Fries, U. S. A.; Colonel W. H. Bartholomew, Great Britain; Charles Moureu and Prof. A. Mayer, France; Lieutenant-Colonel N. Pentimalli, Italy; Major-General H. Haraguchi, Japan.

Ford and Edison Inspect Muscle Shoals

Mr. Ford and his engineers, accompanied by Thomas A. Edison, are making a thorough inspection of the nitrate and water-power projects at Muscle Shoals. One particular object of the investigation is to estimate as exactly as possible the hydro-electric power capacity of the project. Mr. Ford believes 1,000,000 hp. can be developed there and expects to show by data to be collected that his offer to the government of \$28,000,000 for the completion of the Wilson Dam is a liberal one.

Denver to Hold Industrial Exposition

The Colorado Industrial Exposition is to be held at Denver from Feb. 20 to 25 inclusive, under the auspices of the Colorado Manufacturers and Merchants Association. At least twenty Chambers of Commerce throughout the state will have exhibits together with individual manufacturers from every community. These exhibits will be representative of every character of product manufactured in Colorado.

Civil Service Examinations

Open competitive examinations for the following positions are announced by the Civil Service Commission. Vacancies exist in the Bureau of Standards.

Technologist; associate technologist; assistant technologist; junior technologist.

Engineer; associate engineer; assistant engineer; junior engineer.

Physicist; associate physicist; assistant physicist; junior physicist.

For technologist, engineer and physicist the salary range is \$2,800 to \$4,000 a year; for associates, \$2,000 to \$2,800; assistants, \$1,500 to \$2,000; juniors, \$1,200 to \$1,500. Applicants for the junior grades will be required to assemble for a written test on Jan. 11, 1922.

It is also stated that the Bureau of Standards is in need of junior aids and laboratory apprentices. The basic pay offered is \$540 a year for apprentices and \$720 to \$840 a year for aids, to which salaries there is added the increase of \$20 a month granted by Congress.

The Bureau of Standards covers a wide field of work in physics, chemistry, engineering and industrial technology, and offers valuable experience to those preparing for those professions. Junior assistants at the Bureau of Standards are given opportunity to continue their college work at the universities in Washington, the courses of which are largely arranged to suit the conveniences of persons in the government service.

Personal

CURTIS R. BURNETT, an official of the American Oil & Supply Co., Newark, N. J., was re-elected president of the Ironbound Manufacturers' Association at its recent annual meeting, for the third consecutive year.

R. E. EDSALL has resumed his work at the byproduct coke plant of the McKinney Steel Co., after a leave of absence on account of illness.

Dr. MORIN FISHBEIN, editor of the *American Medical Association Journal*, spoke before the Chicago Chemists Club recently on "Chemical Book Plates."

NELSON B. GASKILL, of New Jersey, a Republican member of the Federal Trade Commission, succeeded to the chairmanship of the Commission Dec. 1 for a term of one year. Mr. Gaskill, who was vice-chairman during the past year, succeeds to the chairmanship under the rule of the Commission which provides for rotation in the office of chairman among the several commissioners. Mr. Gaskill was appointed to the Commission in December, 1919, to fill an unexpired term caused by the death of John Franklin Fort.

ARTHUR L. HALVORSEN, chemical engineer, of Perth Amboy, N. J., has just returned from a 5 weeks' visit to chemical plants in Germany and Norway.

A. E. HAY, Canadian sales manager for the Pratt & Lambert Co., Buffalo, N. Y., gave an interesting address before the members of the Buffalo Paint, Oil and Varnish Club, Nov. 25.

Prof. J. H. MATHEWS, director of the course in chemistry at the University of Wisconsin, lectured before the department of chemistry at Oberlin College, on Nov. 30, on the subjects "A General Survey of Photochemistry" and "Color Photography." The following evening he spoke before the Cleveland Section of the American Chemical Society on the subject "Photochemistry and Some of Its Research Problems."

A. V. H. MORY, formerly associated with Sears, Roebuck & Co. and with Procter & Gamble Co., is now engaged in private practice in Chicago, specializing in chemical organization.

F. W. NORTHRIDGE, JR., assistant manager of the export department of the National Aniline & Chemical Co., has resigned.

E. D. TWEEDELL, assistant librarian of the John Crerar Library, spoke before the Chicago Chemists Club recently on the operation and usefulness of a modern scientific library.

HENRY WIGGLESWORTH, director of development for the General Chemical Co. and the Allied Dye & Chemical Corporation, has resigned. He will take an extended vacation in Europe.

Dr. R. W. WOODWARD has resigned as physicist and chief of the section of mechanical metallurgy of the Bureau of Standards, Washington, D. C., to become chief metallurgist for the Whitney Manufacturing Co., Hartford, Conn.

The United States Potters' Association, East Liverpool, Ohio, has announced that FRANK P. JUDGE of the National China Co., Salineville, Ohio, will be elected president of the association at its meeting in Washington, D. C., during the present week, succeeding B. I. Salisbury of the Onondaga Pottery Co., Syracuse, N. Y. Charles F. Goodwin, East Liverpool, Ohio, will be re-elected secretary-treasurer.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Dec. 5, 1921.

The demand for general chemicals during the past week was somewhat irregular, although producers reported a good volume of business from producing channels. Manufacturers of caustic soda and soda ash have not experienced the inquiry they were expecting because of keen competition among first hands. The consuming element had a desire to show more interest in the more important chemicals at prevailing quotations, but producers have shown their desire for new business to a marked extent and buyers in the majority of cases are holding back for new figures. This condition, however, does not hold true for every item, and indications in general point to a gradual increase in the volume of business after the turn of the year. The time is fast approaching for inventory taking, and with this out of the way, all will be ready for a resumption of regular trading. The export business continued to show encouraging developments and additional inquiries were received from various parts of South America and Mexico. Leading factors in the trade are of the opinion that a successful termination of the armament conference will mean a tremendous improvement in our export trade. Importers continued to receive fair-sized shipments of foreign material, but these have had little effect on the spot market, as the big portion has been sent directly into consuming channels on standing contracts. Yellow prussiate of potash, cyanide of soda and bleaching powder have been the most active commodities during the past week. Stocks of these producers appear to be quite scarce, with the demand greatly increased. Chlorate of potash and caustic potash have shown the most weakness in the entire list, with large portions of imported material available at reduced figures.

Producers of 28 per cent *acetic acid* reported sales at 2½c. per lb. The 56 per cent is held at 5½c., while the glacial material varied from 9½@11c. per lb., according to quantity and seller. The market has not shown any new developments during the past month on this product and producers have found their main outlet among consumers holding regular contracts. Most sellers of *formaldehyde* were not eager to quote under 11c. per lb. for spot material in barrels. It is quite possible that several odd lots could be picked up around a fraction below prevailing quotations. The demand has not been very heavy during the interval and dealers were eager to dispose of some of their spot supplies. *Oxalic acid* closed firm at 14½@15c. per lb., according to seller. Holders stated that the inquiry had materially improved since the advance in producers' figures at the works. Market conditions in *tartaric acid* appear easier, and sellers were offering crystals down to 26½c. per lb., with the powdered variety offered at 27c. Goods coming in from abroad were quoted at 25c. per lb. c.i.f. New York. Manufacturers'

prices remained unchanged. Leading producers of *Glaubers salt* quote \$1.25 per 100 lb. for single bags in carload quantities and up to \$1.40 in smaller lots. Barrels were quoted at \$1.40 per 100 lb. in carload lots. Second hands offered occasional lots of imported goods a trifle below producers' quotations. The conditions in the *bleaching powder* market remained quite steady and prominent sellers reported a good inquiry from the consuming trade. Sales were reported at \$2.25 per 100 lb. for large containers and 2½c. per lb. for small drums, f.o.b. works, in carload quantities. Spot material is rather scarce and dealers were firm in their quotations at 2½c. per lb. for large drums. Imported bleach was held around \$2.10 per 100 lb. ex-dock New York. First-hand sales of *sodium sulphite* were reported at \$3.65 @ \$3.75 per 100 lb. in carload lots f.o.b. works. Sales of smaller quantities were made up to 4c. per lb. Prices for light *soda ash* in single bags were quoted around \$1.98 @ \$2.10 per 100 lb., according to seller. Imported material was quoted at \$1.75 @ \$1.80 for 100 lb. Ash in barrels sold down to \$2.35 per 100 lb. The spot market was somewhat dull during the week, as purchasers have shown an inclination toward works material. Manufacturers quote \$1.45 per 100 lb., basis 48 per cent, f.o.b. works, in carload quantities for the single bags. *Prussiate of potash* has improved to a considerable extent and the market is decidedly firmer, with spot offerings very scarce. Sales early in the week were reported at 22 @ 22½c. per lb., with 22½c. reported on inside figure at the close. The demand for spot *caustic soda* was quite irregular and the market closed easy. Occasional offerings were heard around the trade at \$3.90 @ \$4 per 100 lb. Buyers in general were not anxious to pay over \$3.90 for larger quantities. Producers, on the other hand, reported a steady inquiry for material, with frequent sales at prevailing levels. A fair export demand has featured the market during the week. Spot *bichromate of soda* was quoted at 8c. per lb. for small lots. It was intimated that a few odd lots might be purchased a fraction below the regular quotation, although indications were very encouraging for firm prices. Quiet trading in *nitrite of soda* was reported among leading sellers. The market in most directions was quoted at 6½ @ 7c. per lb., while firm business at 6½c. would in all probability be accepted.

COAL-TAR PRODUCTS

The export inquiry in the coal-tar products market during the past week was surprisingly encouraging. Japan has come into the market again as a large purchaser of phenol and orders have been around the market for large-sized quantities. The demand from fur dyers has been quite active in the past few days and with an early settlement in garment trade entanglements, this branch of the market should show material strength in prices and demand. Aniline salt showed considerable improvement, as did paranitraniline and naphthalene. There was much surprise expressed at the new prices named by manufacturers of *naphthalene*. The contract quotations for 1922 are given at 6½c. per lb. for the flakes and 7½c. for the balls. This announcement has had a stimulating effect on spot prices and holders were not anxious to quote under 7c. per lb. for spot material. *Benzene* production is gradually coming around and with the increase in steel production the market on this commodity will again become normal. First hands still quote 27 @ 33c. per gal. for future delivery. Spot stocks are exceedingly light and most buyers have been unable to locate any supplies. The *phenol* market has been the leading feature of the coal-tar products division. Exporters with large orders have experienced extreme difficulty in finding prime material at the prices demanded by foreign interests. It seems that spot stocks are the remains of left-over war goods which have been in containers for several years and in the majority of cases have turned into a solid mass of off-colored brown. First hands quote the market at 15c. per lb., with resale material held around 10c. per lb. Government surplus stocks are quoted at 12c. per lb. Supplies of *paranitraniline* in second hands are becoming scarce. Inquiries have materially increased and the market has again become steady at 77 @ 80c. per lb. **Producers of H acid** are offering this product as low as \$1 per lb. but resale lots have sold considerably below this

level. Competition is very keen and some producers have found it impossible to keep up with the present low quotations. The demand is not heavy and orders are mostly for small quantities. Conditions in the *aniline oil* market are somewhat firmer since the scarcity of benzene. The general quotation is 18c. per lb., with 19 @ 20c. asked for smaller lots. Sellers of *diethylaniline* ask \$1 per lb. with several orders recorded down to 95c. per lb. The demand is not very active. The market on *diphenylamine* is steady at 60 @ 65c. per lb., depending upon seller and quantity. Inquiries were decidedly better during the past week.

The Chicago Market

CHICAGO, Dec. 1, 1921.

The condition of the chemical market in this district is about the same as has been noted for several weeks. All factors continue to report a good volume of business and are apparently satisfied. It is noticeable that buyers are confining their purchases to parcels that will be consumed by the first of the year and large business can scarcely be expected to materialize until after that time. All indications show that chemical inventories in consumers' hands will be very small this year, which makes the outlook for after the first of the year very bright. Prices for the past two weeks have as a rule held quite firm and there was a noticeable stiffening of quotations in some directions. This is particularly noticeable on imported material, as the situation abroad makes it very difficult to estimate the cost of replacement stocks.

GENERAL CHEMICALS

Caustic soda is not so firm on spot, although quotations are unchanged at \$4.75 per 100 lb. for the ground 76 per cent and \$4.25 for the solid. These figures could very likely be shaded somewhat for a quantity order. *Soda ash* continues to move in a routine way at \$2.60 per 100 lb. for material in cooperage. *Sal ammoniac* is firm, with supplies none too plentiful. The white granular is held at 8 @ 8½c. for spot stock, and it is doubtful if this could be bettered for ordinary quantities. *Carbon bisulphide* continues firm at 7 @ 7½c. per lb. *Carbon tetrachloride* is also in a firm position, with only moderate supplies available at 10½ @ 11c. per lb. *Glycerine* is very firm at the new advance recently announced by refiners, and 15c. per lb. for c.p. material in drums is the prevailing quotation. *Formaldehyde* is quiet, with supplies offered as low at 11c. per lb. for single barrels. *Mercury* is one of the firmest items on the list and only a few small lots were available at \$47 per flask.

Bichromates are moving in a routine way and are unchanged at 14c. for the *potash* and 8½ @ 9c. for the *soda*. *Carbonate of potash* is rather dull and one lot of 80-85 per cent calcined was offered at 6c. per lb. *Caustic potash* is moving fairly well at 6½c. per lb. for 88-92 per cent material. *Chlorate of potash* is rather scarce and 8½c. per lb. for the crystals was the best offer noted. The powdered was available in small quantities at 7½c. *Sodium bicarbonate* is plentiful and unchanged at \$2.60 per 100 lb. There was a fair demand for *borax* and supplies were available at 6c. per lb.

The acids are enjoying a fair demand and supplies are plentiful but could scarcely be called large. *Acetic acid* is unchanged at 2½c. for the 28 per cent commercial in barrels and 10 @ 10½c. for the glacial. *Oxalic acid* is moving well at 15½ @ 16½c. per lb. The heavy acids are firm, with *muratic*, 18 deg., at \$1.50 per 100 lb. in carboys and *nitric* at 6c. *Sulphuric acid* is offered at \$18 @ \$20 per ton in tank cars f.o.b. works.

VEGETABLE OILS

Linseed oil has failed to show any marked improvement during the past few days. There is only a fair movement and today's quotations were 77c. per gal. for the boiled and 75c. for the raw, lots of 1 to 3 drums.

NAVAL STORES

Naval stores remained in a firm position for the past few days and business was reported as good. *Spirits of turpentine* are enjoying a good demand, and small lots are quoted at 86c. per gal., drum basis. *Rosins* are unchanged as to price and appear to be moving in a fair way.

The Iron and Steel Market

PITTSBURGH, Dec. 2, 1921.

The finished steel markets continue to exhibit decided dullness, except that in tubular goods there is fully as heavy demand as formerly, while in tin plate there are fairly heavy engagements for first quarter deliveries. What has been suspected in the past few weeks is now made clear, that the usual year-end dullness of the steel market has this year come ahead of time. There is, however, an extenuating circumstance, for it has become evident now that in the past couple of months, when common report was that sales and purchases were only for current shipment, there was a fair volume of contract business done to the end of the year, and this contract business is helping to sustain mill operations at rates far above what would be required to execute the new business being booked from day to day.

In the case of a few commodities a key to the situation mentioned, as to the existence of contracts, is furnished by the yielding of the quoted market price, not to a new low level, but to a price which it is explained was done some time ago. An instance of this is furnished by hoops, bands and hot-rolled strips, which for a while were quoted at 2.25c., base, but are again obtainable at 2c., possibly at a trifle less.

Mill operations have begun to decrease, though the decrease to date is small. Measured in steel ingot output, the decrease is only a few points, as ingot production is estimated at between 40 and 45 per cent of capacity, against an average of 44 per cent in October and a slightly higher rate on Nov. 1. Production of finished steel has probably decreased in greater ratio, since during September and October very considerable tonnages of ingots and semi-finished steel, stocked earlier in the year, were rolled into finished products. Stocks of raw material and intermediate products are now quite thoroughly liquidated, except for large piles of iron ore and perhaps some moderate sized stocks of pig iron.

Of the various branches of the finished steel industry the pipe mills easily lead in point of activity, showing operations of from 60 to 80 per cent. Sheet and tin plate mills come next in point of activity, while wire mills show a moderate rate of operation. Bar, shape, plate and rail mills are relatively inactive.

STEEL PRICES

The steel market is strongly competitive in practically all branches, though for the time being at least prices are stabilized in tin plate and sheets, at \$4.75 for 100-lb. coke tin plate, 2.25c. for blue annealed sheets, 3c. for black sheets and 4c. for galvanized sheets. The American Sheet & Tin Plate Co. named these sheet prices a week ago, for deliveries through the first quarter, after independents had withdrawn various cut prices below the level indicated. In tubular goods the shading that has been in evidence almost since the reduced lists were issued Sept. 16 is more widespread, but has not gone deeper, an exception being line pipe which apparently has been selling at less than the cost of production. Bars, shapes and plates are quotable in general at a range of 1.50@1.60c.

PIG IRON AND COKE

The pig-iron market continues very dull, with no material changes in quotable prices. Unfortunately for the market, the failure of prices to exhibit change is ascribed chiefly to the absence of inquiry that would produce competition and an effort on the part of sellers to obtain business. For instance, while the valley market remains quotable at \$20 for bessemer, \$19 for basic and \$20.50 for foundry iron, some furnaces make no secret of the fact that they would welcome an opportunity to shade these prices to get a good-sized order, say one for 5,000 tons.

The Connellsville coke market has grown weaker still, spot furnace having become practically nominal at \$3, while foundry coke rarely sells at above \$4 and draws that price only with difficulty. Production by the merchant ovens in the Connellsville region has decreased fully 25 per cent in the past 5 weeks, while there is no evidence that the rate of consumption has decreased or that production is below consumption now, from which it seems clearly to follow that in the past few weeks a very considerable surplus has been produced.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.12½ - \$0.12½	\$0.40 - \$0.45

Calcium peroxide.....lb.		1.40 - 1.50
Calcium phosphate, tribasic.....lb.		.15 - .16
Camphor.....lb.		.91 - .95
Carbon bisulphide.....lb.	.06½ - .06½	.07 - .07½
Carbon tetrachloride, drums.....lb.	.10½ - .10½	.11 - .12
Carbonyl chloride, (phosgene).....lb.		.60 - .75
Caustic potash (see potassium hydroxide)		
Caustic soda (see sodium hydroxide).....		
Chlorine, gas, liquid-cylinders(100 lb.) lb.	.08 - .09	.09½ - .10
Chloroform.....lb.		.40 - .43
Cobalt oxide.....lb.		2.00 - 2.10
Copperas (see iron sulphate).....		
Copper carbonate, green precipitate.....lb.	.19 - .19½	.20 - .21
Copper cyanide.....lb.		.50 - .62
Copper sulphate, crystals.....lb.	.05½ - .05½	.05½ - .06
Cream of tartar(see potassium bitartrate)		
Epsom salt (see magnesium sulphate).....		
Ethyl Acetate Com. 85%.....gal.		70 - 80
Ethyl Acetate pure (acetic ether, 98% to 100%).....gal.		95 - 112
Formaldehyde, 40 per cent.....lb.	.10½ - .11	.11½ - .12
Fusel oil, ref.....gal.		2.50 - 3.00
Fusel oil, crude.....gal.		1.50 - 1.75
Glauber's salt (see sodium sulphate).....		
Glycerine, C. P. drums extra.....lb.		.14½ - .15
Iodine, resublimed.....lb.		3.50 - 3.60
Iron oxide, red.....lb.		.12 - .18
Iron sulphate (copperas).....ton	18.00 - 19.00	20.00 - 23.00
Lead acetate.....lb.	.15 - .15½	.15½ - .16½
Lead arsenate, powd.....lb.		.15 - .20
Lead nitrate.....lb.	.08 - .08½	.08½ - .09
Litharge.....lb.		1.40 - 1.50
Lithium carbonate.....lb.	.08 - .08½	.09 - .10
Magnesium carbonate, technical.....lb.	2.50 - 2.75	
Magnesium sulphate, U. S. P. 100 lb.		1.10 - 1.75
Magnesium sulphate, technical.....100 lb.		.66 - .68
Methanol, 95%.....gal.		.70 - .72
Methanol, 97%.....gal.		.12 - .12½
Nickel Salt, double.....lb.		.14 - .14½
Nickel salt, single.....lb.		
Phosgene (see carbonyl chloride).....		
Phosphorus, red.....lb.	.45 - .46	.47 - .50
Phosphorus, yellow.....lb.		.32 - .35
Potassium bichromate.....lb.	.11 - .11½	.11½ - .12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$0.28 — \$0.30	
Potassium bromide, granular..... lb.	.15 — .20	
Potassium carbonate, U. S. P..... lb.	.15 — .16	
Potassium carbonate, 80-85%..... lb.	.04 — .06	
Potassium chlorate, crystals..... lb.	.05 — .06	
Potassium cyanide..... lb.	.40 — .45	
Potassium hydroxide (caustic potash)..... lb.	.05 — .06	
Potassium iodide..... lb.	2.60 — 2.75	
Potassium nitrate..... lb.	.07 — .07	
Potassium permanganate..... lb.	.17 — .18	
Potassium prussiate, red..... lb.	.28 — .29	
Potassium prussiate, yellow..... lb.	.22 — .22	
Rochelle salts (see sodium potas tartrate).....		
Salammoniac (see ammonium chloride).....		
Salt soda (see sodium carbonate).....		
Salt cake (bulk)..... ton	19.00 — 21.00	
Silver cyanide..... oz.	1.10 — 1.20	
Silver nitrate..... oz.	.45 — .46	
Soda ash, light..... 100 lb.	1.90 — 2.00	
Soda ash, dense..... 100 lb.	2.25 — 2.30	
Sodium acetate..... lb.	.04 — .04	
Sodium bicarbonate..... 100 lb.	2.00 — 2.25	
Sodium bichromate..... lb.	.08 — .08	
Sodium bisulphate (nitre cake)..... ton	5.00 — 5.25	
Sodium bisulphite powdered, U.S.P..... lb.	.04 — .05	
Sodium borate (borax)..... lb.	.05 — .06	
Sodium carbonate (salt soda)..... 100 lb.	1.80 — 1.90	
Sodium chlorate..... lb.	.07 — .07	
Sodium cyanide..... lb.	.28 — .28	
Sodium fluoride..... lb.	.11 — .12	
Sodium hydroxide (caustic soda)..... 100 lb.	3.90 — 4.00	
Sodium hyposulphite..... lb.	.03 — .03	
Sodium nitrite..... lb.	.06 — .07	
Sodium peroxide, powdered..... lb.	.25 — .26	
Sodium phosphate, dibasic..... lb.	.04 — .04	
Sodium potassium tartrate (Rochelle salts)..... lb.	.14 — .14	
Sodium prussiate, yellow..... lb.	.14 — .14	
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 — 1.05	
Sodium silicate, solution (60 deg.)..... 100 lb.	2.30 — 2.40	
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.30 — 1.50	
Sodium sulphide, fused, 60-62 per cent (cone.) lb.	.04 — .04	
Sodium sulphite, crystals..... lb.	.03 — .03	
Strontium nitrate, powdered..... lb.	.13 — .14	
Sulphur chloride, red..... lb.	.06 — .06	
Sulphur, crude..... ton	18.00 — 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 — .08	
Sulphur (sublimed), flour..... 100 lb.	2.25 — 3.10	
Sulphur, roll (brimstone)..... 100 lb.	2.00 — 2.75	
Tin bichloride..... lb.	.09 — .09	
Tin oxide..... lb.	.37 — .38	
Zinc carbonate, precipitate..... lb.	.16 — .16	
Zinc chloride, gran..... lb.	.09 — .09	
Zinc cyanide..... lb.	.42 — .44	
Zinc dust..... lb.	.11 — .11	
Zinc oxide, XX..... lb.	.07 — .07	
Zinc sulphate..... 100 lb.	3.00 — 3.25	

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 — \$1.15
Alpha-naphthol, refined..... lb.	1.25 — 1.30
Alpha-naphthylamine..... lb.	.30 — .32
Aniline oil, drums extra..... lb.	.18 — .20
Aniline salts..... lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.35 — 1.45
Benzidine, base..... lb.	.90 — 1.00
Benzidine sulphate..... lb.	.75 — .85
Benzoic acid, U.S.P..... lb.	.62 — .65
Benzoate of soda, U.S.P..... lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 — .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 — .28
Benzyl chloride, 95-97%, refined..... lb.	.25 — .27
Benzyl chloride, tech..... lb.	.20 — .23
Beta-naphthol benzoate..... lb.	3.75 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75
Beta-naphthol, tech..... lb.	.30 — .34
Beta-naphthylamine, sublimed..... lb.	1.75 — 1.85
Cresol, U. S. P., in drums (100 lb.)..... lb.	.15 — .16
Ortho-cresol, in drums (100 lb.)..... lb.	.24 — .26
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 — .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 — .50
Dichlorobenzene..... lb.	.06 — .09
Diethylaniline..... lb.	.95 — 1.10
Dimethylaniline..... lb.	.45 — .60
Dinitrobenzene..... lb.	.23 — .27
Dinitrochlorobenzene..... lb.	.20 — .25
Dinitronaphthalene..... lb.	.30 — .35
Dinitrophenol..... lb.	.35 — .40
Dinitrotoluene..... lb.	.25 — .30
Dip oil, 25%, car lots, in drums..... gal.	.30 — .35
Diphenylamine..... lb.	.60 — .70
H-acid..... lb.	1.00 — 1.10
Meta-phenylenediamine..... lb.	1.10 — 1.15
Mono-chlorobenzene..... lb.	.12 — .14
Monoethylaniline..... lb.	1.65 — 1.70
Naphthalene crushed, in bbls..... lb.	.07 — .08
Naphthalene, flake..... lb.	.07 — .08
Naphthalene, balls..... lb.	.08 — .09
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35
Nitro-toluene..... lb.	.15 — .17
Ortho-amidophenol..... lb.	3.00 — 3.10
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.77 — .80
Ortho-nitro-toluene..... lb.	.15 — .20
Ortho-toluidine..... lb.	.20 — .25
Para-amidophenol, base..... lb.	1.40 — 1.45
Para-amidophenol, HCl..... lb.	1.70 — 1.80
Para-dichlorobenzene..... lb.	.12 — .15
Paranitroaniline..... lb.	.75 — .80
Para-nitrotoluene..... lb.	.80 — .85
Para-phenylenediamine..... lb.	1.70 — 1.75
Para-toluidine..... lb.	1.25 — 1.40
Phthalic anhydride..... lb.	.40 — .50

Phenol, U. S. P., drums..... lb.	.10 — .15
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	1.50 — 1.60
Resorcinol, pure..... lb.	2.00 — 2.25
Salicylic acid, tech., in bbls..... lb.	.20 — .21
Salicylic acid, U. S. P..... lb.	.22 — .23
Salol..... lb.	.70 — .72
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 — .16
Sulphanilic acid, crude..... lb.	.27 — .30
Tolidine..... lb.	1.30 — 1.35
Toluidine, mixed..... lb.	.43 — .45
Toluene, in tank cars..... gal.	.25 — .28
Toluene, in drums..... gal.	.28 — .31
Xylidines, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.40 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax..... lb.	\$0.20 — \$0.21
Beeswax, refined, dark..... lb.	.24 — .25
Beeswax, refined, light..... lb.	.28 — .30
Beeswax, white pure..... lb.	.34 — .38
Candellilla wax..... lb.	.24 — .24
Carnauba, No. 1..... lb.	.45 — .46
Carnauba, No. 2, North Country..... lb.	.23 — .23
Carnauba, No. 3, North Country..... lb.	.14 — .14
Japan..... lb.	.21 — .21
Montan, crude..... lb.	.04 — .04
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 — .04
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.03 — .03
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 125 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 — .04
Paraffine waxes, refined, 133-135 m.p..... lb.	.05 — .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 — .06
Stearic acid, single pressed..... lb.	.09 — .09
Stearic acid, double pressed..... lb.	.09 — .09
Stearic acid, triple pressed..... lb.	.10 — .10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.55 — 5.60
Rosin E-I..... 280 lb.	5.60 — 5.65
Rosin K-N..... 280 lb.	6.20 — 6.75
Rosin W. G.-W. W..... 280 lb.	7.00 — 7.25
Wood rosin, bbl..... 280 lb.	6.25 — .
Spirits of turpentine..... gal.	.80 — .
Wood turpentine, steam dist..... gal.	.78 — .
Wood turpentine, dest. dist..... gal.	.76 — .
Pine tar pitch, bbl..... 200 lb.	6.00 — .
Tar, kiln burned, bbl. (500 lb.)..... bbl.	10.50 — .
Retort tar, bbl..... 500 lb.	10.50 — .
Rosin oil, first run..... gal.	.36 — .
Rosin oil, second run..... gal.	.39 — .
Rosin oil, third run..... gal.	.46 — .
Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	\$1.90 — .
Pine oil, pure, dest. dist..... gal.	1.50 — .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 — .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 — .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 — .
Pine tar, ref., thin, sp.gr., 1.080-1.060..... gal.	.35 — .
Turpentine, crude, sp.gr., 0.900-0.970..... gal.	1.25 — .
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35 — .
Pinewood creosote, ref..... gal.	.52 — .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 — .
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 — .
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 — .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 — .

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.30 — 2.90
Blood, dried, f.o.b., N. Y..... unit	4.00 — .
Bone, 3 and 50, ground, raw..... ton	30.00 — 32.00
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 — 3.00
Nitrate soda..... 100 lb.	2.30 — 2.35
Tankage, high grade, f.o.b. Chicago..... unit	2.75 — 3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.e..... ton	4.50 — 6.50
Tennessee, 78-80 p.e..... ton	8.50 — 9.00
Potassium muriate, 80 p.e..... ton	37.00 — 40.00
Potassium sulphate..... unit	.90 — 1.00

Crude Rubber

Para-Upriver fine..... lb.	\$0.21 — .22
Upriver coarse..... lb.	.13 — .14
Upriver cauchoball..... lb.	.13 — .13
Plantation—First latex crepe..... lb.	.17 — .18
Ribbed smoked sheets..... lb.	.17 — .18
Brown crepe, thin, clean..... lb.	.15 — .
Amber crepe No. 1..... lb.	.17 — .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 — \$0.10
Castor oil, AA, in bbls..... lb.	.11 — .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 — .13
Cocoanut oil, Ceylon grade, in bbls..... lb.	.09 — .09
Cocoanut oil, Cochin grade, in bbls..... lb.	.10 — .10
Corn oil, crude, in bbls..... lb.	.08 — .08
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 — .07
Cottonseed oil, summer yellow..... lb.	.08 — .09
Cottonseed oil, winter yellow..... lb.	.09 — .09

Linseed oil, raw, car lots (domestic).....	gal.	.65	—	.66
Linseed oil, raw, tank cars (domestic).....	gal.	.60	—	.61
Linseed oil, in 5-bbl lots (domestic).....	gal.	.68	—	.69
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palin, Lagos.....	lb.	.07 $\frac{1}{2}$	—	.07 $\frac{3}{4}$
Palm, Niger.....	lb.	.06 $\frac{1}{2}$	—	.06 $\frac{3}{4}$
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.08 $\frac{1}{2}$
Peanut oil, refined, in bbls.....	lb.	.11 $\frac{1}{2}$	—	.11 $\frac{3}{4}$
Rapeseed oil, refined in bbls.....	gal.	.83	—	.84
Rapeseed oil, blown, in bbls.....	gal.	.88	—	.90
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08 $\frac{3}{4}$	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07 $\frac{1}{2}$	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.45	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$23.50	—	28.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	15.00	—	17.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04 $\frac{1}{2}$
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.15	—	.16
Chalk, Precipitated, domestic, extra light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04 $\frac{1}{2}$
Chalk, Precipitated, domestic, heavy.....	lb.	.03 $\frac{3}{4}$	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, Precipitated, English, light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04 $\frac{1}{2}$
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude, f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.06	—	.07
Graphite, Ceylon chip.....	lb.	.04 $\frac{1}{2}$	—	.05
Graphite, high grade amorphous crude.....	lb.	.00 $\frac{3}{4}$	—	.02 $\frac{1}{2}$
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr, f.o.b. N.Y.....	per ton	55.00	—	60.00
Magnesite, calcined.....	per ton	50.00	—	65.00
Pumice stone, imported.....	lb.	.03	—	.40
Pumice stone, domestic, lump.....	lb.	.05	—	.05 $\frac{1}{2}$
Pumice stone, domestic, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1 $\frac{1}{2}$ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.68	—	.70
Shellac, orange superfine.....	lb.	.78	—	.80
Shellac, A. C. garnet.....	lb.	.58	—	.60
Shellac, T. N.....	lb.	.68	—	.70
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	7.50	—	11.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$50.00		
Carborundum refractory brick, 9-in. { less than earlot	1,000	1250.00		
Chrome brick, f.o.b. Eastern shipping points.....	net ton	52- 55		
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30- 32		
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	33- 35		
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	35- 40		
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30- 35		
Magnesite brick, 9-in. straight.....	net ton	65- 70		
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77		
Magnesite brick, soaps and splits.....	net ton	98		
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	40- 42		
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	42- 45		
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35- 38		

Ferro-Alloys

All f.o.b. Works

Ferrocobalt-titanium, 15-18% C, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	225.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Paper Co. has awarded a contract to C. M. Allen & Son, Birmingham, for the construction of a 1-story plant, 100 x 190 ft., for the manufacture of corrugated paper boxes and kindred products, estimated to cost about \$75,000. Of this amount, approximately \$40,000 will be used for the machinery installation. T. M. McClellan is president.

GADSDEN—The Gadsden Clay Products Co. has commenced work on its extension and improvement program, to include the installation of three down-draft kilns, with capacity of about 150,000 bricks; drying plant of waste-heat type, and other department extensions. It is proposed to develop an output of about 40,000 bricks per day. Gordon Hood is treasurer and general manager.

Connecticut

WINDSOR LOCKS—The J. N. L. Smythe Co., 32-34 South Sixth St., Philadelphia, Pa., manufacturer of paper products, has acquired the plant and business of the Windsor Locks Paper Mills, Windsor Locks. The new owner plans for extensions in the mill to double the present capacity.

Florida

EUSTIS—Adam J. Walz, Fort Mason, near Eustis, is organizing a company to establish a local plant for the manufacture of pressed bricks. Steam-operated presses, drying apparatus and other equipment will be installed.

Illinois

CICERO—M. L. Barrett & Co., 233 West Lake St., Chicago, manufacturer of essential oils, will soon commence the erection of a new plant at Cicero, contract for which recently has been awarded to the Kniskern Co., 149 South Dearborn St., Chicago. It will consist of two 1-story buildings, and is estimated to cost about \$100,000, including equipment. H. N. Mulder, Room 1702, 140 South Dearborn St., Chicago, is architect.

Indiana

INDIANAPOLIS—The Beveridge Paper Co. has tentative plans under consideration for the erection of a new building at its plant. It is proposed to begin work next spring. H. L. Beveridge is president.

Kentucky

SOMERSET—The Kentucky Coal & Electro Chemical Co. has preliminary plans under way for the erection of a local chemical manufacturing plant, comprising a group of buildings, estimated to cost about \$500,000, including machinery. The Associated Engineering Co., Somerset, is engineer.

LOUISVILLE—The Dosch Chemical Co. has acquired a local plant totaling over 15 acres of floor space, for the establishment of a new works for the manufacture of lime sulphur, rubber sulphur, sulphite solutions and other chemical products. A large department will be operated for the manufacture of insecticides, as well as for the production of machinery for spraying, dusting, etc., with chemical solutions. The machinery and equipment installation at the plant is estimated to cost in excess of \$200,000. Theodore Dosch is president of the company.

Louisiana

BOGALUSA—The Bogalusa Paper Co. is planning for the construction of a large addition to its local paper mills, erected several years ago and representing an investment of about \$2,000,000. The proposed extension will duplicate, in part, the present mill and is estimated to cost close to \$1,000,000, with machinery. W. H. Sullivan is president.

Maryland

BALTIMORE—The Adamentex Brick Co., recently organized with a capital of \$1,000,000, has acquired property on the Sulphur

Springs Road, Towson, totaling about 25 acres of land, as a site for the erection of its proposed plant for the manufacture of sand-cement bricks. It is proposed to provide buildings and equipment for an initial daily production of about 200,000 bricks. The company is represented by Blum & Makover, Equitable Bldg. L. F. Ducker is president.

Massachusetts

FITCHBURG—The Crocker-Burbank Co., manufacturer of paper products, has perfected plans for extensions and improvements in its mill, estimated to cost in the neighborhood of \$100,000, including machinery which will be installed.

PEABODY—Buddell & Harrigan, manufacturers of leather products, have acquired the local plant of the Formal Leather Co., for the establishment of a works for the production of chrome white leather, with daily output to approximate 200 dozen skins. The company will also continue operations at its plant in the Ingraham Bldg., and plans to increase the facilities of this factory.

Michigan

PLAINWELL—The Otsego Angle Steel Co. has construction under way on a 1-story plant, 40 x 200 ft., and plans for the early occupancy of the structure.

RIVERROUGE—The American Brick & Tile Co., recently organized, has acquired a tract of land totaling about 16 acres, adjoining the plant of the Ewing Bolt & Screw Co., with about 600 ft. of frontage on the Rouge River. It will be used as a site for the erection of a brick- and tile-manufacturing plant, with facilities to provide for the employment of about 500 operatives at the start. Preliminary plans are under way.

Missouri

FERGUSON—The Republic Photographic Co., Kansas City, Mo., is perfecting plans for the early erection of its proposed plant at Ferguson, and will soon break ground for different buildings. It will be equipped for the manufacture of sensitized paper specialties. The main building will be 78 x 160 ft., with chemical laboratory, 54 x 250 ft., adjoining; a complete paper drying department will be installed, as well as power plant for factory operation. The complete plant is estimated to cost in excess of \$200,000. Albert F. H. Seelig, 2194 Railway Exchange Bldg., St. Louis, is engineer. E. B. Fish is president.

New Jersey

MATAWAN—The Mosaic Tile Co. has awarded a contract to Walter V. Patton, 273 Main St., for the erection of two 1-story additions to its plant, 60 x 138 ft. and 27 x 182 ft., respectively, for increased production. Work will be commenced at once, and it is proposed to have the buildings ready for machinery at an early date. Headquarters of the company are at Zanesville, O., and Walter Miller, regularly located there, will supervise the construction and equipment installation.

LAMBERTVILLE—The Lambertville Pottery Co., manufacturer of sanitary ware, has commenced the construction of a new kiln at its plant.

LAMBERTVILLE—The Perseverance Paper Mill Co. will make a number of improvements in its local mill, prior to a resumption of production during the coming months. New equipment will be installed in different departments, and present machinery repaired and overhauled. It is planned to remodel certain portions of the mill.

New York

NEW YORK—The Robinson Stoneware Co., 226-36 Newell St., has filed plans for the rebuilding of the portion of its plant recently destroyed by fire. The work is estimated to cost about \$20,000.

ALBANY—The Hires Turner Glass Co., Philadelphia, has completed the erection of its branch plant on Tivoli St., near Broadway, and operations have been commenced. A manufacturing department will be maintained for the production of mirrors, beveled window glass, etc.

Ohio

EAST PALESTINE—The National Fireproofing Co., Fulton Bldg., Pittsburgh, Pa., will rebuild by day labor its plant at East Palestine, recently destroyed by fire, and excavations for the main building, 160 x 100 ft., are under way. The work will cost about \$60,000. Sidney F. Heckert, Bessemer Bldg., Pittsburgh, is architect.

CLEVELAND—The Carbo-Oxygen Co. has construction under way on an addition to its local plant, devoted to the manufacture of carbo-hydrogen gas, for the manufacture of oxygen gas. Similar additions will be erected, also, at the company plants at Columbus, O.; Bayonne, N. J.; Corapolls, Pa.; and Chicago, Ill., and initial work has been commenced. At Buffalo, N. Y., work is proceeding on a new plant for the manufacture of carbo-hydrogen gas and oxygen gas. To carry out the details of the expansion, the company has arranged for a preferred stock issue of \$2,000,000. J. C. Trees, Pittsburgh, Pa., is president.

Oklahoma

DEWEY—The Dewey Portland Cement Co., Mutual Bldg., Kansas City, Mo., has awarded a contract to the MacDonald Engineering Co., 53 West Jackson Boulevard, Chicago, Ill., for the erection of an addition to its plant at Dewey, estimated to cost about \$60,000. Work will be commenced at an early date.

TULSA—The Producers & Refiners Corp. is perfecting plans for the erection of a wax lubricating and grease plant at its oil refinery at West Tulsa.

Pennsylvania

PHILADELPHIA—Fire, Nov. 18, destroyed a portion of the lamp black and carbon manufacturing plant of the L. Martin Co., Raleigh St., with loss estimated at about \$100,000, including equipment. It is said that the plant will be rebuilt.

PITTSBURGH—The Birmingham Mirror Co., 2014 Josephine St., manufacturer of mirrors and other glass specialties, has tentative plans under consideration for enlargements in its plant.

PHILADELPHIA—The United Oxygen & Mfg. Co., Bath and Westmoreland Sts., has filed plans for the erection of a 1-story plant.

Tennessee

KNOXVILLE—The Knoxville Glass Co. has arranged for the construction of a 1-story plant, 90 x 100 ft., for the manufacture of mirrors and other glass products.

Texas

BEAUMONT—The Humphreys-Pure Oil Co., Dallas, is planning for the construction of a new refinery at Beaumont. The local Chamber of Commerce is interested in the project. Paul Gage will be in charge of erection. A. E. Humphreys is president.

MCGREGOR—The Koury Calcium Co., recently organized with a capital of \$400,000, has acquired property near McGregor, totaling about 150 acres of land, as a site for the erection of a plant for the manufacture of lime products. The proposed works will have a capacity of about 1,000 bbl. of finished material a day, and are estimated to cost close to \$100,000, including machinery. Michael Koury is president of the company, and W. V. Hanover secretary.

CAMERON—The Owens Refinery Co., Ardmore, Okla., is perfecting plans for the immediate erection of a local oil-refining plant, with initial output of about 1,500 bbl. a day. Local offices will be established in the First National Bank Bldg.

Utah

SALT LAKE CITY—The Industrial Potash Corp. is perfecting plans for the erection of a new mill, estimated to cost close to \$1,500,000, including machinery. A bond issue for this amount has been arranged to carry out the details of the project.

Washington

SEATTLE—The Commonwealth Finance Co., Securities Bldg., is arranging details for the formation of a new company, which will build a local plant for the manufacture of soap products. The company will be capitalized at \$250,000 and headed by C. H. Colson. Negotiations are under way for a lease of property on Westlake Ave., as a site for the new factory.

Wisconsin

MILWAUKEE—The Wadhams Oil Co., 359 Clinton St., has construction under way on a new oil refinery at Thirty-third and Burnham Sts., estimated to cost about \$100,000, with equipment. S. S. Cramer is president.

New Companies

THE SCANLON LEATHER CO., Boston, Mass., has been incorporated with a capital of \$25,000, to manufacture leather products. J. Frank Scanlon, 233 Purchase St., is president; and George Strangman, Swampscott, Mass., treasurer.

E. F. DREW & CO., INC., New York, has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical by-products. The incorporators are T. P. Durrell, R. Dadd and C. S. Soule. The company is represented by Hun, Parker & Reilly, Albany.

THE GREENBERG BOTTLE CO., Newark, N. J., has been incorporated with a capital of \$100,000, to manufacture bottles and other glass products. The incorporators are Samuel B. Ferster, Wesley B. King and Herman W. Brams, 800 Broad St., Newark.

THE PLANT, THEIS & GOULD PAPER CO., 30 North La Salle St., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture paper products. The incorporators are William M. Plant, Robert S. Theis and George W. Gould.

THE SILVER LEAF PETROLEUM CO., Fort Worth, Tex., has been incorporated with a capital of \$250,000, under Delaware laws, to manufacture petroleum products. The incorporators are J. P. Haley and C. I. Barfield, Fort Worth; and G. E. Wilson, Mineral Wells, Tex. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE GOLDEN STATE COLOR & CHEMICAL WORKS, INC., Long Beach, Cal., has been incorporated with a capital of \$25,000, to manufacture chemicals, colors and affiliated products. The incorporators are J. S. Reardon, R. L. Buffum and J. V. Nevin, Long Beach.

THE LAGLER PAPER PRODUCTS CO., INC., New York, has been incorporated with a capital of \$40,000, to manufacture paper goods. The incorporators are D. R. Daly, O. Wuest and H. G. Smith. The company is represented by York & York, 7 Dey St.

THE HOLLAND GLASS WORKS, INC., 615 West Monroe St., Chicago, Ill., has been incorporated with a capital of \$40,000, to manufacture brass and bronze products. The incorporators are Frank J. and F. B. Liska.

THE LINCOLN OIL CO., Wilmington, Del., has been incorporated under state laws with capital of \$2,000,000, to manufacture refined oil products. The company is represented by the Delaware Registration Trust Co., 900 Market St.

THE CHARLES F. MARTIN LUBRICATING CO., Tulsa, Okla., has been incorporated with a capital of \$10,000, to manufacture lubricating oils, greases, etc. The incorporators are D. D. and Charles F. Martin, and A. F. Hoffman, Jr., all of Tulsa.

THE TWIN CITY LEATHER CO., Gloversville, N. Y., has been incorporated with a capital of \$40,000, to manufacture leather products. The incorporators are F. W. and M. Shire, and B. W. Draums, Gloversville. The company is represented by T. Haviland, Gloversville.

THE TITAN STEEL TUBE CO., 4851 North Springfield Ave., Chicago, Ill., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture steel tubing. The incorporators are William Smith and Martin Swanson.

THE PORCELAIN APPLIANCE CORP., Parkersburg, W. Va., has been incorporated with a capital of \$25,000, to manufacture porcelain specialties, including electrical porcelain products. The incorporators are J. H. Parker, Parkersburg; H. R. Holmes, East Liverpool, O.; and R. G. Spencer, Carey, O. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE PEARL OIL CO., Jamestown, N. Y., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are P. W. Goodwin, E. W. Olson and C. O. Johnson. The company is represented by J. R. Rogerson, 136 Bartlett Ave., Jamestown.

THE SOLIDONE MFG. CO., Newark, N. J., has been incorporated with a capital of \$125,000, to manufacture chemicals and chemical byproducts. The incorporators are I. S. Fleitell, Charles Schaezle and Simon W. Gordon, 183 Lillie St., Newark.

THE TARX CHEMICAL CO., 348 East Illinois St., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are L. E. Harding, W. C. Waggoner and W. S. Carson.

THE BULLION CHEMICAL CO., Memphis, Tenn., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are Howard Brode and Isadore Bullion, both of Memphis.

THE W. E. FRANKS OIL CO., New York, has been incorporated with a capital of \$105,000, to manufacture refined oil products. The incorporators are F. Anderson, I. Randall and W. E. Franks, New York. The company is represented by W. J. Kenny, New Brighton, S. I.

CHENY & CO., INC., New York, has been incorporated under Delaware laws with capital of \$500,000, to manufacture magnesium cements and other plastic materials. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE OWENS & TRAEGER CARTON CO., Hoboken, N. Y., has been incorporated with a capital of \$200,000, to manufacture folding paper boxes and cartons, and other paper specialties. The incorporators are Frank E. Kolb, Christopher W. Traeger and Clarence M. Owens, 1100 Adams St., Hoboken.

THE FRANCE-UTAH OIL CO., Salt Lake City, Utah, has been incorporated under Delaware laws with capital of \$5,000,000, to manufacture refined petroleum products. The incorporators are J. W. Musser and D. H. Gustavsen, Salt Lake City. The company is represented by the Corporation Service Co., Wilmington, Del.

Industrial Notes

THE ESSENTIAL OIL SPECIALTIES CO., Philadelphia, Pa., has changed its name to the Essential Oil Co., and moved its offices to Mulberry and New York Ave., Trenton, N. J.

THE AETNA EXPLOSIVES CO. has been succeeded by the Hercules Powder Co. The advertising, purchasing and traffic departments are at Wilmington, Del., and the branch sales office is at 120 Broadway, New York City.

THE RAYMOND BROS. IMPACT PULVERIZER CO., Chicago, Ill., has located a permanent Eastern office at 50 Church St., New York City. S. B. Kanowitz will be in charge.

THE POWDERED COAL ENGINEERING & EQUIPMENT CO. moved its offices and manufacturing plant from Chicago to Buffalo, N. Y., on Nov. 1. The personnel of the organization has been somewhat changed and H. B. Pruden has been elected as chairman of the board and J. W. Lansing of Buffalo has been elected president. The new board of directors of the company is as follows: J. W. Lansing, Fenton M. Parke, J. E. Finley, Harry R. Wait, J. C. Trefts, H. B. Pruden, B. W. Wistar, W. M. Faber and Stephen T. Lockwood.

THE POWDERED COAL DEVELOPMENT CORP. has been organized, with headquarters at Omaha, Neb. This company controls the Pruden patents for the burning of pulverized coal in the western half of the United States. The company is actively engaged in financing and erecting central pulverizing plants and installation of equipment for burning pulverized coal. Byron B. Oberst, formerly with the Interstate Oil & Refining Co., is president of the new corporation. The board of directors includes R. M. Robertson, construction engineer, American Smelting & Refining Co.; A. E. Hall, manager Omaha plant, American Smelting & Refining Co.; Joseph C. Weeth, president of the Harmon Weeth Coal Co.; J. J. Dodds, president of the Dodds Lumber Co.; Bert Phillips, formerly chief engineer, Collis Products Co., Omaha plant, and Irving H. Arey, with the Republic Metal Ware Co.

THE HARDINGE CO., New York, announces that H. A. Kimber, formerly of the Quigley Furnace Specialties Co., is now in charge of the sales of the Quigley pulverized fuel department of the Hardinge Co., in New York, N. Y. L. W. Marso, who is in charge of the branch office of the Quigley Furnace Specialties Co., located at 427 Oliver Bldg., Pittsburgh, Pa., will continue in the Pittsburgh office under the name of the Hardinge Co., but will specialize in the handling of the Quigley pulverized fuel systems, which department has been acquired by the Hardinge Co. from the Quigley Furnace Specialties Co.; O. M. Rau, formerly consulting engineer to the Philadelphia Rapid Transit Co., has become associated with the Hardinge Co., and will specialize in the handling of Quigley pulverized fuel systems as applied to boilers. W. O. Renkin has become associated with the Hardinge Co., New York, N. Y., in the capacity of managing engineer of the Quigley pulverized fuel department.

THE UNITED STATES CAST IRON PIPE & FOUNDRY CO., Burlington, N. J., announces the opening of a new office at 811 Dixie Terminal Bldg., Cincinnati, O. P. T. Laws, assistant works manager, will make this point his headquarters. Sales from this office will be in charge of Harold G. Henderson.

Capital Increases, Etc.

THE SUPREME PAPER BOX CO., 10 Forest St., Brooklyn, N. Y., has filed notice of increase in capital from \$25,000 to \$50,000.

THE POWERS-WEIGHTMAN-ROSENGARTEN CO., 916 Parrish St., Philadelphia, Pa., manufacturer of chemicals, has filed notice of decrease in capital stock from \$3,390,000 to \$1,700,000.

Reorganization plans are being perfected by officials of the **REPUBLIC RUBBER CO.**, Youngstown, O. A change in capitalization and stock issues will be made.

THE R. L. GREENE PAPER CO., Providence, R. I., has filed notice of increase in capital from \$50,000 to \$500,000.

THE OIL PRODUCTION CO., Houston, Tex., has filed notice of increase in capital from \$55,000 to \$75,000.

THE GOODYEAR TIRE & RUBBER CO., Akron, O., has disposed of a bond issue of \$27,500,000, the proceeds to be used for general operations, expansion, etc. E. G. Wilmer is president.

THE W. R. HOLLINGSHEAD CHEMICAL CO., a Delaware corporation, has filed notice of intention to operate in New York, with capital of \$1,000,000, for the manufacture of chemical products, with headquarters at Binghamton. W. R. Hollingshead and C. M. Reynolds, Binghamton, represent the company.

THE TOWNS PAINT CO., 222 Pearl St., Buffalo, N. Y., has filed notice of increase in capital from \$100,000 to \$200,000.

Officials of the **NATIONAL LEATHER CO.**, 161 South St., Boston, Mass., are arranging reorganization plans for the company, to include a preferred stock issue of \$15,000,000. The common stock will be reduced from 3,000,000 to 750,000 shares.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 26 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS is holding its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters are at the Emerson Hotel.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN PETROLEUM INSTITUTE is holding its second annual meeting at the Congress Hotel, Chicago, Dec. 6, 7 and 8.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Dec. 9—American Chemical Society, regular meeting; Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Administrative and Business

Opinions on Tariff Policy

TARIFF, always much in the public eye, is just now directly in the spotlight of legislative, administrative and business interest. With the resumption of Congressional sessions, the Senate resumes its hearings on the tariff bill; the President in his message to Congress comments at length upon the tariff situation; and the Chamber of Commerce of the United States begins to take the vote of its member organizations on a referendum regarding seven important recommendations as to tariff policy. Surely no one can say that the subject is being neglected.

In one important particular the message of the President and the recommendations of the tariff policy committee of the national Chamber of Commerce agree—namely, that there should be a flexibility for administrative regulation of tariff rates. Speaking to this point, the President recommends obtaining flexibility through “the extension of the powers of the Tariff Commission so that it can adapt itself to a scientific and wholly just administration of the law.” The committee recommendation is: “Legislation should permit, in the event of changes of economic factors, adjustment of tariff rates by administrative authorities within limits prescribed by Congress for the purpose of maintaining a consistent tariff policy,” and the committee also recommends “creation of a tariff adjustment board to administer adjustable rates.”

Although not identical in phrasing or in implication of the agency which should administer an adjustable or flexible tariff rate, both of these recommendations recognize what is now clearly established as a fact, that we cannot arbitrarily today fix a tariff rate for many commodities without almost certainly encountering great disadvantage therefrom within the next few years, if indeed not within the next few months. There clearly is now established in the minds of many the belief that the principal economic facts and laws must sooner or later govern tariff adjustments and that the system of political tariff revision to suit the constituencies of the most influential legislators is in the long run, even for these particular constituencies, a bad policy.

In another particular the comment of the President and the recommendations of the Chamber of Commerce committee agree in part at least—namely, with respect to the proposal of “American valuation” of imports. The President points out that an arbitrary adoption of this basis of duties would be hazardous. But the Chamber of Commerce committee, with only one dissenting vote out of the twelve committeemen, recommends that “the present system of valuation for levy of ad valorem duties should be maintained and the so-called American valuation should not be adopted.”

It is more and more coming to be realized that tariff protection is not an unmixed blessing even to those industries which are “protected.” The opportunities

existing for interruption of foreign trade by protective tariff rates fixed on anything like a rigid or permanent basis is too great to be risked at the present time. All agree that anti-dumping legislation of some type is essential, and that reasonable protection for American industries subject to destructive competition will be of general benefit to the country whenever those industries are on a sound economic footing; but even the most ardent advocates of protection are now apparently beginning to waver in their advocacy of general high protective rates. Industries that have been counting upon such rates must, therefore, begin to put their house in order for living on a different basis.

Senate to Investigate

The Dye Industry

WE ARE to be regaled with a Senate investigation of the dye industry in the United States in an effort to discover monopoly on the part of American manufacturers and alleged lobbying and other nefarious activities on the part of importers of German dyes and their agents. Senator KING of Utah introduced the original resolution, which provided only for ferreting out the domestic monopoly, but Senator FRELINGHUYSEN of New Jersey shrewdly brought sufficient pressure to bear on the Senator from Utah to make him accept an amendment to extend the investigation to the so-called German dye lobby. Of course, Senator MOSES of New Hampshire supported the original King resolution and demonstrated by means of a large map suspended from the public gallery the extent of the control exercised by the alleged American monopoly in this country. Curiously enough, the center of this control was a large red spot marking the location of Wilmington, Del., with the word “du Pont” printed in the center of the red circle. It has become habit with Senator MOSES to see red whenever the dye business is mentioned, and he could readily be counted upon to join in the chase.

Thus the whole dye business in this country is to be laid bare to public gaze and we have Senator FRELINGHUYSEN to thank for making the investigation comprehensive. Like most investigations, it will probably engage in needless excursions into unrelated subjects, but we express the hope that even though the Senatorial committee may get off the track, American dye manufacturers will insist on keeping the two purposes clearly in mind so that we may know beyond a doubt whether there is a domestic dye monopoly and a perniciously active lobby of agents of German dye manufacturers.

It is not improbable that the dye embargo will come in for its share of the discussion, and we urge upon American manufacturers the merit of considering ways and means for placating the opponents of the embargo by suggesting the appointment of a board of review with an impartial chairman whose duty it shall be to determine when the embargo should be enforced. There is no doubt that it will be impossible to get a tariff law

high enough to keep out German dyes. It is equally certain the embargo will be the only effective measure, but its opponents must be given assurance that it can and will be administered fairly and efficiently. For our part we welcome the investigation and doubt not that American dye manufacturers will welcome it also if it is sincerely conducted.

Ceramic Engineers

Develop Clay Industries

DISCUSSIONS of an industry by those who have a broad view of the field are apt to contain statements far more sweeping than actual facts justify. For instance, it is often said that while the art of burning clay has been practiced for many centuries the application of science in ceramic industries is woefully lacking. Now this is true in measure, particularly if the research phase in pure science is considered. We do have much to learn about colloids, plasticity, electrochemical effects and the eutectics of clay mixes in the burning. But so are other industries in the adolescence of youth as regards scientific fundamentals.

Ceramic engineers, though only recently so named, are the true technologists. They have never failed to come forward when needed on plant problems. They were the first to use regeneration and recuperation in burning processes. During the French Revolution they developed continuous firing. The American chemist developed architectural terra cotta to a stage where the Wrigley and Woolworth type of building is an accomplished fact. Optical glass production, originally centered at Jena, has been surpassed in quantity and quality in America. Further examples might be given of recent work done by the Bureau of Standards, the Bureau of Mines, the teaching staffs and graduates of our ceramic schools. Movements under way to develop engineers from plant operators in the pottery industries selecting for intensive education many of the fine young chaps who have generations of clay-working experience in the blood and who must otherwise remain mere mechanics is a laudable and logical procedure.

Ceramics must be thought of as one of the fields where engineering deeds are making for worth-while progress.

Helium Demonstrates

Commercial Utility

IN THE demonstration of the navigability of an airship filled with helium, the C-7 of the Navy flew successfully on several short test flights around Hampton Roads and then made a trip to Washington and return as a complete answer to the feasibility of floating an airship with helium, which has approximately 92 per cent of the lifting power of hydrogen. The event will give an impetus to aviation with lighter-than-air craft and may be expected to stimulate the government's activities in the production of helium from certain of our natural gases. We believe that the Helium Board is in possession of information pointing to the existence of comparatively large percentages of helium in some natural gases not yet exploited, and with the determination of a policy as to the best method of production we may look for a renewed and more successful campaign. Incidentally it is worth recording that advocates of lighter-than-air craft foresee a large development in commercial aviation with gas-filled ships, despite the fact that this phase of the industry has apparently lagged behind airplane development.

National Income

and Its Distribution

THE National Bureau of Economic Research, a non-partisan body and one apparently without material bias, numbering among its directors WALTER R. INGALLS and GEORGE E. ROBERTS, has made a study of "Income in the United States," the report being now in press. Undoubtedly many men have wished they could see a presentation of what our collective income is and who gets it. At intervals, in non-census years, the Bureau of the Census estimates the total "wealth" of the United States, and in connection with the census it ascertains the number of persons engaged in gainful occupations, although it does not attempt to ascertain how gainful the occupations are.

The presentation now available states for each of the years 1910 to 1911 inclusive: (1) The total national income, in dollars; (2) the same, per capita; (3) the total, reduced to "1913 dollars" and thus representing in substance the quantity of goods or services involved, and (4) the same, per capita.

According to the figures, the total income increased falteringly from 31.4 billion dollars in 1910 to 36.0 billions in 1915, then sharply and continuously to 65.9 billions in 1919. On account of increasing population, the per capita income of \$340 in 1910 increased scarcely at all to 1915, but rose to \$629 in 1919.

Reducing the dollars to the 1913 basis, and thus representing the quantity of business done rather than the money return, the curve takes a different shape. Instead of ascending continuously, it reaches a maximum in 1916 and 1917, then descends. On account of the increase in population, the per capita ascends more gradually and descends more rapidly. It was \$349 for 1910, increasing to \$400 in 1916 and then descending to \$358 in 1919.

The presentation undertakes to show the division of income between investors and management on the one hand and those receiving wages and salaries on the other. The division shifts from 31-69 in 1910 to 26-74 in 1914, then swings the other way to 33-67 in 1916 and then reacts to 23-77 in 1918. The bureau intends eventually to furnish figures for 1919 and later years.

These figures may not be precisely accurate, but they cannot be far out. They may be said to supply a long-felt want. For instance, there has been the oft-repeated statement which many thinking men have been disposed to question, that in the last analysis labor gets 85 per cent of the money turnover. The normal seems to range between a 30 to 70 and a 25 to 75 division.

One of the interesting uses we can make of the figures presented is to make comparison between income and wealth. The Bureau of the Census reported the "wealth" of the United States at \$107,104,212,000 for 1904 and at \$187,739,071,000 for 1912. By interpolation we get \$163,000,000,000 for 1910. The national income as reported is 19 per cent of this amount. Our wealth at the time represented the equivalent of income for a trifle more than 5 years.

The United States Chamber of Commerce reported the "wealth" of the United States in 1920 at \$290,464,000,000. Interpolating between this and the census report for 1912, we get \$275,000,000,000 for 1919. The income in actual dollars was 24 per cent of this, while the income reduced to 1913 dollars was 14 per cent. As the figures of wealth cannot have been swelled by the depreciation of the dollar nearly as much as the income was swelled, the ratio between quantity of product and

quantity of things representing wealth was probably about the same as in 1910, approximately 1 to 5.

A still more important use can be made of the figures. Reduced to the standard of the 1913 dollar, the per capita income was \$349 in 1910 and \$358 in 1919. That means, if it means anything, that in 9 years we came to work harder or more efficiently by only 2.6 per cent. We made practically no progress. With better methods, improved equipment and greater personal efficiency, we should have come in 9 years to produce a great deal more per capita. We have a great and expensive war to pay for and we have to work hard and efficiently to accomplish the task.

Haber, Nernst

And the Amenities of Life

IT MADE us wince last year when the Nobel prize for 1919 was awarded to Professor HABER. Now we learn that the 1920 award goes to Professor NERNST. We comforted ourselves in regard to the Haber award with the belief that, after all, it was NERNST who was really the chief offender against his nation's solemn vow and against the faith of mankind by the introduction of the art of poisoning into warfare. As for HABER, we thought that he had merely trailed along behind NERNST. Of course after the miserable business was begun everybody had to engage in it, and no onus attaches to those who participated in it later.

But there wasn't any invention or merit in the use of poison to kill enemies. If this were an honorable thing to do, we might all be carrying wreaths to the tomb of the late LUCREZIA BORGIA. The selection of chlorine or phosgene or mustard gas or any of the other poisons was in no case a masterstroke. When the German leaders in military and physical science resolved upon it they were bound by their nation's plighted word not to do so. It was when they broke it that they offended against national honor and proved themselves to lack those inhibitions which, throughout the ages, men of good will have been trying to establish and conserve. This lack is the true criminal quality. The killing of soldiers by poison when all the world had agreed not to do it ranks along with the invasion of Belgium as a contributing cause to the present degeneration of faith.

We knew NERNST to be a leader in this crime, but we resolved for lack of certainty in regard to HABER to be lenient with him. HABER quit the service with the rank of Captain, whereas NERNST was made a Count of the German Empire by the Kaiser. Our later information is to the effect that NERNST and HABER were active rivals in this sorry business. Both men are great chemists. Both, for services rendered before their days of crime, were abundantly entitled to the great honor of the Nobel prize. We do not question the merit of these two awards on the ground of achievement in chemistry before the war. The point that we make is that their later participation in the great offense against humanity may be construed as the very reason for the awards of merit that now accrue to them from Sweden. This is not our belief. But public opinion is a curious thing, and it does not listen to explanations. It connects the names of NERNST and HABER with the preparation of the German gas attacks, and now it connects the same names with the Nobel prizes. The whole proceeding seems to us unfortunate and contrary to the intent of ALFRED NOBEL, who established the Foundation. It seems also unfair to the eminent men who received the great prize before, by putting them into such company.

Ford and Edison

Inspect Muscle Shoals

MESSRS. FORD and EDISON have recently made an inspection trip to Muscle Shoals in connection with Mr. FORD's offer for the nitrate plants and water-power development. Doubtless they found the plants in good standby condition, for they were so left by the Army officers and engineers at the time that the termination of hostilities in Europe spoiled a lot of good business in America. Likewise they must have found a good piece of work well started at the site of the Wilson Dam. So much any laymen could well undersand in "inspecting" these overinspected properties, as the politicians who reported to Mr. FORD well knew.

Just there, however, we suspect, ends the value of an inspection trip by these gentlemen. When asked what he thought of Mr. FORD some time ago, one of our beloved statesmen replied that he was a successful manufacturer of low-priced automobiles. Likewise, all are aware of the fact that THOMAS A. EDISON is a successful organizer of scientific research. It is doubtful, however, if any conservative business concern would seriously retain either gentleman as an expert in engineering or economics relating to water-power or nitrate plants. Probably, then, this junket was a bouquet-throwing affair arranged by the politicians local to Florence and Sheffield, Ala., who may be behind the Ford offer.

Equally unbusinesslike have been all conditions surrounding the Ford offer for Muscle Shoals. After the manner of the State St. or East Side trader, a snap offer asking special privileges on the water power and a \$5,000,000 bid for a plant layout costing \$100,000,000, the farce of inspection is entered into with Mr. EDISON acting as Mr. FORD's engineer. The old clothes man will give a dollar for the scarcely used dress suit, and the housewife may accept in the husband's absence. A pittance for Muscle Shoals is "good business" for Mr. FORD, but poor stewardship on the part of government officials if they accept.

It is not necessary or desirable that Muscle Shoals be sold on a single bid.

Water Power Development

Shows Impetus Under New Law

IN THE first report of the Federal Power Commission we get an insight into the degree to which the country was ready for the federal water-power act of 1920. Although it had been in existence only 16 months at the time the report was made, the commission had received 270 applications covering the possible development of over 16 million horsepower. The capital expenditure required to complete these projects would exceed in the aggregate two billion dollars. But the report is not concerned alone with prospects. Construction under license is now under way on seven projects for the development of 557,800 primary and 1,276,400 installed horsepower. In addition to this, the commission has authorized twenty-seven preliminary permits and thirty-one licenses, involving 1,415,600 primary and 2,627,000 installed horsepower. These are impressive figures, particularly for the period of industrial depression through which we have passed. Under the circumstances the Federal Power Commission may be pardoned for feeling that hydro-electric power development will be the outstanding industrial fact of the next quarter of a century.

Readers' Views and Comments

Sound Ingots and Rails as a Matter of Course

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with great interest the communication of Sir Robert Hadfield, appearing in *CHEMICAL & METALLURGICAL ENGINEERING* of Oct. 26, 1921, and although I am in entire accord with Sir Robert that "sound ingots will result in sounder rails," I cannot agree with him that production of sound ingots has not had a full and proper chance of being investigated and tested on a large scale in America. I also must take exception to his intimation that the American practice of producing sound steel ingots has been attempts to follow or copy his system. At the present time, though steel production is very light, there is being produced in large or so-called tonnage mills approximately 100,000 tons of sound steel ingots per month by a distinctly American method, which, I am certain, does not use any of the features patented by Sir Robert Hadfield.

Our methods for producing sound steel do, however, employ the fundamentals which are essential to the production of sound homogeneous ingots, namely:

First. That the bath of metal be thoroughly deoxidized before teeming, so that no marked chemical reaction takes place during solidification.

Second. That the metal be cast in an ingot mold whose inside dimensions are enough greater at the top to prevent internal bridging of the shrinkage cavity.

Third. That the ingot be kept in substantially a vertical position until solidification is complete.

Fourth. That a suitable refractory sink-head be used.

Sir Robert Hadfield's method, as I understand it, specified a fifth—namely, to place a solid fuel or heating material on top of the sink-head portion of the ingot and to keep this fuel at a high temperature by means of a blow-pipe or forced draft. This latter provision I do not consider fundamentally essential, as we are daily making many heats of 3- to 4-ton ingots in which the sound product in bloom or billet averages over 90 per cent of the total weight of the ingot.

My work during the past 10 years for the betterment of steel ingots may not be strictly classified as original research work, as many of the results obtained by me were previously predicted by Henry M. Howe and Bradley Stoughton in their pioneer work with wax ingots in 1906-07 and were indicated by DeLavell in a Swedish patent of 1881. Such work as I have contributed to the art and science of the production of sound steel ingots has primarily been that of carrying out in a feasible mechanical manner, with new apparatus, the methods and theories advanced in a broad manner by Messrs. Howe and Stoughton, so that sound ingots can be commercially produced without interference with production.

The rounded concavo-convex bottom of an ingot I have found absolutely essential in the prevention of cleavage planes, which are the potential cause of most butt-cracks and internal flaws in the lower portion of ingots cast on flat stools, as used, I believe, by Sir Robert Hadfield and as has usually been the practice with all large ingots in tonnage production. The metal of the bottom of such ingots, which theoretically should be the soundest, is frequently full of internal flaws.

The manifest advantages of the big-end-up mold type are now so well known and generally understood, both as to benefits obtained in the reduction of shrinkage cavity or pipe and in the reduction and lifting of axial segregation, that it is not necessary to specify them.

It may be well to state specifically the important patented features of the Gathmann ingot mold, and these are indicated as follows:

A. Heavy, heat-absorbing walls at the lower and lighter mold walls at the upper portion of the ingot.

B. Concavo-convex rounded bottom of mold integral with the body or side walls of mold, to prevent cleavage planes at the base of the ingot, and to allow stripping without danger of finning underneath the mold walls.

C. Suspended conical base closure plug whereby the ingot may be moved upward in the mold.

D. Metal plate seal for preventing sticking of ingot to the stripping plug.

The above substantially are the important features which I have worked out for mass production of big-end-up ingots such as produced in large tonnage by American practice. I have also found that the sink-head of refractory material should be as nearly the maximum diameter of the ingot as may be workable in any specific mold, and that the volume of the sink-head should be at least 10 per cent of the total volume of the fluid ingot in order to assure that segregation of a harmful nature is all contained within the sink-head after solidification of the ingot. This results in approximately 94 per cent of sound steel in body of the ingot.

It might be of interest to your readers to have Sir Robert Hadfield plainly state the important patented features of his mold and of the British practice for producing sound ingots, and I trust that a public letter from him may be forthcoming specifically pointing out the patented features covered by him which he considers essential to carry out the British method of sound steel production.

That rail steels are still generally made from the cold top pyramidal big-end-down ingot is not because the rail manufacturer is unaware that molds and methods are in daily use which could be applied to the production of rail ingots and assure of the soundness of the rails, but is, I believe, primarily caused by the undoubted increased expense of suitably and thoroughly deoxidizing the bath of metal before teeming. This deoxidation unquestionably adds materially to the cost of the production and finishing of the steel, and rail makers, with but few exceptions, prefer to use a steel which is not thoroughly deoxidized, since the latter yields a larger tonnage at less cost per ton.

The railroads are fundamentally responsible for this condition, as it is within their power to specify that the ingots from which the rails are rolled shall be *thoroughly* deoxidized as well as the present knowledge of the art may permit. Buyers of other high-grade products do thus specify, and the steel maker, be it of rails or any other product, will, I feel certain, be governed largely by the requirements of the buyer.

EMIL GATHMANN,

Baltimore, Md.

Vice-President and General Manager,
Gathmann Engineering Co

Endurance of Steel Under Repeated Stresses

Fatigue Tests on Many Commercial and Alloy Steels Develop No Evidence of "Endurance Limit"—
Ultimate Tensile Strength Closely Related to Endurance Stress at 100 Million Cycles—
Special White-Souther Machine and Semi-Logarithmic Graphs Used

BY D. J. MCADAM, JR.

Metallurgist, U. S. Naval Engineering Experiment Station

FOR several years the subject of endurance of steel under repeated stresses has been investigated at the U. S. Naval Engineering Experiment Station. This investigation has included a variety of carbon and alloy steels that have been heat-treated in various ways. For each type of steel, in addition to the endurance tests, tension, torsion, hardness and impact tests have been made.

ENDURANCE TESTING MACHINE

In the endurance tests described in this paper, the test specimen was arranged as a rotating cantilever beam. During every revolution of the specimen under test, it was subjected to definite alternate tension and compression.

The machine used for this purpose has been developed at the U. S. Naval Engineering Experiment Station. It is a modification of the White-Souther machine. As shown in Fig. 1, this machine is composed of units each capable of testing four specimens at once. Although

holder is due to L. E. Foster, assistant foreman of the Naval Engineering Experiment Station. As shown in Fig. 3 the outer end of the tapered sleeve is threaded so that the hexagonal nut *N* can be attached; knurled nut *O* is then adjusted. By means of the interaction of these two nuts the tapered sleeve *L* holding the specimen *E* may be forced into or removed from the hollow tapered specimen holder *D*.

This method of inserting and removing the test specimen is far superior to the method used in the original White-Souther machine. The violence necessary in inserting and removing the specimen by the old method soon put the surfaces of tapered sleeve and sleeve holder in such condition that the specimen was not properly centered and consequently wobbled when revolved. By use of the improved method, however, the hardened surfaces of tapered sleeve and sleeve holder remain true indefinitely, and the centering of the specimen is so accurate that from a distance of several feet it is difficult to see whether or not the specimen is revolving.

FIG. 1. GENERAL DRAWING OF ENDURANCE TESTING MACHINE

Fig. 1 shows two units on the same side of the motor *C*, the units at the Naval Experiment Station are assembled so that the motor is between two units.

Each of the rotating hollow specimen holders *D* holds two test specimens *E*. Adjustable weights *F* are suspended from the end of every test specimen by means of the rods *G* attached to the ball bearings *H*. Below and at right angles to the specimen holders is a long shaft *I* driven by the motor *C*. Specimen holders are rotated by means of spiral gears *J* on the shaft and on the outside of the hollow cylinders. By means of the clutches *K* the rotation of any specimen holder may be started or stopped while the motor shaft is rotating at full speed.

An enlarged view of one of the specimen holders is shown in Fig. 2. It will be noticed that the hollow specimen holder *D* and the sleeve *L* that surrounds the test specimen *E* are each tapered. The tapered sleeve is split, nearly to the inner end, so that it will fit both specimen and holder.

The method of inserting and withdrawing the specimen and tapered sleeve from the hollow tapered specimen

Early in this investigation it was found that if the load is allowed to act on a test specimen while starting or stopping the machine, the specimen is usually bent so that it is of no further use. For a successful endurance test the load must act on the specimen only while it is rotating at full speed. Evidently at a speed somewhat less than the usual running speed corresponding to the

FIG. 2. DETAIL OF SPECIMEN HOLDER

natural frequency of vibration of the weighted specimen, there is excessive vibration of the weighted specimen. The frequency of vibration varies inversely with the load applied and with the types of specimen used is evidently below the usual running speed for loads above about 50 lb. Since the loads used were usually considerably greater than 50 lb., the critical speeds in these investigations were probably always below the actual running speed. Nevertheless, to dampen any synchronous vibrations and diminish their frequency, the weights were suspended by means of helical springs in all the later experiments.

Apparatus, not shown in Fig. 1, was developed for automatically removing the load from the specimen when the speed slackens or the machine stops, consisting of a system of counter-weights, levers and magnetic release. It was developed by L. E. Foster and John Amoss of the Experiment Station.

TEST SPECIMEN

The test specimen originally used in this investigation was of type A shown in Fig. 3. The left end, when under test, is gripped by the tapered sleeve, and is large enough to be used for a tension or alternating torsion test after the rotating cantilever endurance test is finished. In type A (Fig. 3) under test, the maximum stress is at the end of the $\frac{1}{2}$ -in. fillet. The

FIG. 3. DIMENSIONS OF ENDURANCE TEST SPECIMENS

finishing tool used was shaped so as to fit the fillet at the plane of maximum stress; sharp tool marks in the region of maximum stress were thus avoided. Very light cuts were taken in finishing, and the greatest care was taken in the entire machining process.

Although type A specimens, made as thus described, gave results as consistent as could apparently be expected in endurance tests, an improved type of specimen was later developed and used. In the improved type of specimen the portion subject to stress is conical instead of cylindrical. The taper is so adjusted that the maximum stress, instead of being at the end of the fillet, is in any desired plane *M* as illustrated by types B to E.

Moreover, while in type A specimens the stress falls off rapidly with distance from the plane of maximum stress, in the other specimens the taper can be so adjusted that the stress is nearly uniform over a considerable length of the specimen.

The principle used in designing the tapered specimen is as follows: If a cantilever beam is made of such shape that the surface is a cubic-paraboloid, the maximum stress will be uniform throughout its entire length. Machining a test specimen to such a shape would

FIG. 4. DETERMINING TAPER AND LOCATION OF PLANE OF MAXIMUM STRESS

evidently be impracticable. Fortunately, however, simple tapered specimens can be so designed that their conical surfaces are tangent to a cubic-paraboloid at any desired plane, as illustrated by Fig. 4. For any such cubic-paraboloid the line *CD*, connecting any two opposite points of tangency, is one and one-half times as long as the line *EF*. In a conical specimen of longitudinal section *ABFE*, all points on the surface except those in the plane passing through *CD* are outside the cubic-paraboloid; *CD* is, therefore, the plane of maximum stress. But, since the conical surface for some distance on either side of the plane of maximum stress in these specimens does not differ greatly from the surface of the corresponding cubic-paraboloid, the stress over a considerable part of the entire length is nearly uniform.

Variation of stress with distance from the plane of maximum stress in the various types of specimen is shown in Fig. 5. Comparison makes it evident that the uniformity of stress is much greater in the tapered specimens than in the type A specimen. In types B, C and D, moreover, the variation of stress over about $1\frac{1}{2}$ in. of the specimen length is slight.

CONCENTRATION OF STRESS AT THE FILLET

The stress at the end of the fillet, even after the most careful machining, is undoubtedly somewhat above the theoretical value. It seemed desirable, therefore, to adopt a type whose plane of maximum stress is so far from the fillet that the specimen will not break there. In such a specimen, the theoretical stress at the fillet would be enough below the maximum stress to offset the excess stress due to the fillet.

To determine the best type of specimen to use, and at the same time to get information in regard to the influence of the fillet in increasing the actual stress beyond the theoretical value, a series of endurance tests was made on specimens of the various types, although these comparative tests were not made until after type A specimen had been in use for some time. Specimens of the various types were made from round rods of mild steel heat-treated in three different ways and stressed sufficiently to cause breakage after a comparatively few revolutions.

The results may be summarized as follows: Of two type B specimens, both broke at the fillet. Of twelve type C specimens, only two broke at the fillet. Of seven type D specimens, only one broke at the fillet. Of four

type *E* specimens, none broke at the fillet. In types *C* to *E* the stress distribution is such as to overcome the excess stress due to the fillet. Since, as shown in Fig. 5, the stress distribution is more uniform in type *C* than in the other types, this was finally adopted for use instead of the original type *A*. Since in this specimen the stress over a length of about 1½ in. does not vary more than about 1½ per cent, it might be expected that, due to slight irregularity of material, fracture may occur anywhere within these approximate limits. It has been found that the position of fracture may vary

FIG. 5. RELATIVE STRESS IN TAPERED SPECIMENS

throughout several inches of the length of the specimen. Though some type *C* specimens break at the fillet, about as many specimens break at an equal distance the other side of the plane of maximum stress, so it seems probable that the fillet has practically no influence.

The comparative tests on various types of specimen have given some indication of the amount of the excess stress due to the fillet. This excess stress is evidently greater than ½ per cent, the drop in stress in type *B* specimen from the plane of maximum stress to the fillet, but less than 1½ per cent, the corresponding drop in stress in type *C* specimen. It was finally decided that a correction of 1 per cent should be added to the theoretical fiber stress values in all type *A* specimens.

MATERIAL

The Bethlehem Steel Co. co-operated in this investigation by furnishing nearly all the material, R. M. Bird of this company giving valuable aid in suggesting and making provisions for suitable material. It was furnished in the form of rolled rods about 13 ft. long and 1¼ in. to 1½ in. in diameter. The American Rolling Mill Co. also supplied bars of "Armco" ingot iron.

The material is described in Table I. Chemical analysis is shown in Table II. Nearly every kind of steel was heat-treated by the makers in two different ways, to give proportional limits of alloy steels at about 60,000 and 110,000 lb. per sq.in.

Some of the material furnished by the Bethlehem Steel Co. was annealed at the Naval Engineering Experiment Station. In designating this material, the letter *a* has been added to the marking.

TENSION TESTS

Average results of several tension tests on every kind of material are given in Table III. The tests were made on an Olsen 50,000-lb. machine. The test specimen was of the Navy standard type, having a 2-in. test length and a 0.505-in. test diameter. The extensometer was of Riehle type. For every experiment, a stress-strain diagram was drawn, and from this the proportional limit was obtained. Speeds below proportional limit were 0.0183 in. per minute per inch test length, and 0.117 in. beyond that point.

TORSION TESTS

Average results of individual torsion tests for every kind of material are given in Table IV. The machine used was of Riehle type, having a capacity of 60,000 lb. The specimen has a 3-in. test length and ¾-in. test diameter. In calculating the stresses up to the proportional limit, the equation $T = \frac{\pi}{16} SD^3$ was used, whereas in calculating the maximum stresses the equation $T = \frac{\pi}{12} SD^3$ was used, where *T* represents the torque, *S* represents the stress and *D* represents the diameter of the specimen. Speed of testing below the proportional limit was 1.26 deg. per minute, and 160 deg. above that point.

HARDNESS TESTS

Average results of two Brinell and scleroscope hardness tests on each material are given in Table III. The machine used in the Brinell tests was an Olsen compound lever machine with standard 10-mm. ball, and the diameter of the impression was measured by a micrometer microscope.

CHARPY IMPACT TESTS

Results of Charpy impact tests by the Bethlehem Steel Co. and by the Naval Experiment Station are given in Table V. An American-made Charpy impact machine of 31 kg.-m. capacity was used by the Naval Experiment Station. The test specimen was a notched bar 0.394 x 0.394 x 2.165 in. The notch, 1 mm. wide, extended halfway through the cross-section of the specimen, with radius of curvature at the bottom of the notch of ½ mm. With a few exceptions, the notch was formed by drilling a hole 1 mm. in diameter at the center of the specimen and afterward cutting the notch from the side of the specimen to the hole. Some specimens from three of the alloy steels, however, were so hard that they could not be drilled; in these eight specimens the notch was cut with a V-shaped tool having a ½-mm. radius at the edge.

FREMONT AND IMPACT-SHEAR TESTS

The same table also gives results of impact tests made at the Watertown Arsenal by the Fremont method and at the Naval Experiment Station by the impact-shear method.¹ The latter was developed at the Naval Experiment Station, and uses an unnotched specimen ¼ x ¾ in. in cross-section. By moving this specimen forward

 Fig. 22. Assembly of endurance tests.

after each test several tests can be made on every specimen.

In investigating the endurance of the various kinds of steel as many individual tests were made as time and material would permit. Stresses were so adjusted that fracture occurred after periods ranging from a few thousand to many million cycles. The machines were run day and night and interruption of any test previous to fracture of the specimen was avoided whenever possible.

Graphs illustrating the stress-cycle relations as developed by these tests are shown in Figs. 6 to 21 inclusive. Fig. 22 summarizes all the results shown—these curves have the ultimate strength of the material also noted. Circles represent specimens of type C which were broken; triangles represent broken type A specimens; crosses note the specimen had not failed at the time of writing or when the alternating stress test was discontinued.

Though emery cloth and crocus cloth were used on all the specimens, a special wooden form shaped to fit the specimens and fillet was used to support the abrasive on certain specimens not distinguished on the diagrams. Polishing with emery cloth No. 1 and crocus cloth was in such cases continued for 5 or 10 minutes after the specimen appeared smooth.

When the results of these endurance tests were first plotted, both stresses and cycles were represented by logarithmic co-ordinates. The advantage of logarithmic plotting is that it reduces the ordinates representing cycles to a convenient length. It has, however, the disadvantage that it minimizes stress differences, especially at the higher stresses. Since the determination of the effect of stress variations on endurance is the object of the investigation, this disadvantage of logarithmic plotting is rather serious. For this reason semi-logarithmic plotting was finally adopted, the ordinates being made proportional to the stresses and the abscissas to the logarithms of the numbers of cycles.

DISCUSSION OF RESULTS

Since slight irregularities of material and of surface are inevitable, it is not to be expected that the positions representing the individual results for any one kind of material would lie on a line either straight or curved. In attempting to draw idealized graphs representing stress-cycle relations, mathematical averages alone cannot be used. The exercise of judgment is necessary, due weight being given to the type of specimen and the history of each individual experiment.

Examination of the figures will show that the results obtained with carbon steels are usually less variable than those obtained with alloy steels. A comparison of the carbon steels makes it apparent that increase of carbon content increases the variability of results. Of the alloy steels, the irregularities are greatest in the chromium-nickel and silicomanganese steels. Apparently the irregularities in results are due largely to inevitable slight irregularities in composition or constitution of the metal.

A study of all the endurance test results has revealed no evidence of any abrupt change in direction of stress-cycle graphs throughout the cycle range investigated. The evidence seems to indicate that the idealized graphs should be nearly straight lines. Though the lines should probably not be entirely straight, the curvature should apparently be so slight that at present it can be neglected. Straight lines, have, therefore, been drawn in

what seems to be the most probable location of the idealized graphs.

The slopes of these graphs do not differ greatly, and are always much less than would be expected from a study of the publications of previous investigators. For example, Basquin² gives a number of logarithmic graphs, compiled from the results of various investigators, in which the angles of slope are such as to indicate a drop of 50 per cent or more in endurance stress with each thousand-fold increase in number of endurance cycles. Moore and Seeley³ and Moore and Gehrig⁴ show graphs with the same indications. Their curves were obtained from the investigations of Wöhler, from investigations at the Watertown Arsenal, and those at the University of Illinois.

On the graphs of Figs. 6 to 21, however, the average slope indicates that the average drop in endurance stress with a thousand-fold increase in number of endurance cycles is only about 15 per cent, varying, for the twenty-three kinds of material investigated, from 7 to about 29 per cent. The numerous results of this investigation, therefore, seem to show conclusively that for this type of endurance test the drop in endurance stress with increase in number of endurance cycles is not nearly so rapid as has been previously supposed. The discrepancy between these conclusions and those of previous investigators may possibly be due to the fact that their graphs were drawn from comparatively few individual results. Some of their individual results, if given weight, would materially change the directions of the corresponding graphs.

RELATION BETWEEN ENDURANCE AND PROPORTIONAL LIMIT

Comparisons of the pairs of graphs, Figs. 16 to 20 inclusive, shows that doubling the proportional limit by heat-treatment does not increase the endurance strength in anywhere near the same proportion. In fact, the results of all the experiments have shown conclusively that endurance stress bears no definite ratio to proportional limit. This ratio is greatest in annealed material. In ingot iron and annealed steels of low carbon content, the endurance stress for 100,000,000 endurance cycles is above the proportional limit; indeed, in ingot iron this endurance stress is not far from the yield point. In quenched and tempered material, however, the endurance stress may be less than half the proportional limit. While an annealed mild steel specimen stressed to its proportional limit will run for weeks without breaking, a quenched and tempered steel specimen stressed to anywhere near its proportional limit will show the entire range of temper colors up to deep blue and break in a few minutes.

Heat-treatment increases endurance strength in approximately the same ratio in which it increases ultimate tensile strength. The results of all the experiments seem to indicate that the endurance strength of any steel is rather closely related to its tensile strength. This and other relations are illustrated by Table VI, where are listed the endurance stresses for 10^6 and 10^7 endurance cycles, and the ratios between these two members for each kind of steel, a measure of the slope of the graph. The ratios of the endurance stresses for 10^6 endurance cycles to the values for ultimate tensile

⁴H. F. Moore and A. H. Gehrig, "Some Fatigue Tests of Nickel Steel and Chrome Nickel Steel," *Proc., A.S.T.M.*, 1919, Part II.

stress, Brinell hardness and ultimate torsional stress are also listed in this table.

Ratios of endurance stresses to ultimate tensile stresses are surprisingly constant, in view of the great variety of material tested. The average ratio is 0.44 and the average departure of individual values from the average is only ± 0.033 . The average ratio of endurance stress to Brinell hardness is 222 ± 16 . As would be expected, the constancy in this ratio is nearly as great as that of endurance to ultimate stress. The average ratio of endurance stress to ultimate torsional stress is 0.60 ± 0.057 ; the constancy is about the same as in the ratio of endurance stress to Brinell hardness.

According to Basquin,⁵ the stress-cycle relations for endurance of metals, under two complete stress-reversals per cycle, can be expressed by the exponential equation

$S = \frac{B}{N^q}$, in which S represents the endurance stress, N represents the corresponding endurance cycles, and B is a constant whose value depends on the material. Since this equation can be written also

$$\log S = \log B - q \log N$$

it can be represented on logarithmic co-ordinate paper by a straight line graph. It seems probable, however, that this straight line relationship is only approximate and that the logarithmic graph has a slight curvature with convexity downward. Extensive investigation would be necessary to decide this definitely, including a number of endurance tests extending to at least 500 million cycles.

When graph slopes are as slight as those shown in Fig. 19, a straight line logarithmic graph would remain nearly a straight line if transformed to semi-logarithmic paper. There would, however, be a slight curvature with convexity downward. Any slight downward convex curvature of a logarithmic graph would, therefore, be magnified by transforming it to semi-logarithmic paper. It seems evident, therefore, that the curvature of stress-cycle graphs can be studied best by the latter method of plotting.

EFFECT OF CHEMICAL COMPOSITION ON ENDURANCE PROPERTIES

A study of the figures shows that in general the graphs are located in the order of the ultimate tensile stress values. This relationship might have been predicted from a study of the constancy of the ratios given in Table VI.

In general, chemical composition seems to influence the endurance stress of a steel only as it influences its tensile stress. This rule may, however, be only approximate, since there are a few apparent exceptions shown in the figures. For example, graph M-2 of silicon-manganese steel has a lower position, and graph G of high-chromium steel has a higher position in the series than would be predicted from a comparison of tensile strength values. Further experiments, however, may make it necessary to make some change in the relative position and slope of these graphs.

Comparison of the graphs showing endurance properties of annealed carbon steels and "Armco" ingot iron as received from the manufacturers shows the influence of carbon on the endurance properties of steel. As would be expected, other things being equal, the endurance stress increases with increase in carbon per-

centage, at least within the range investigated. The apparently anomalous position of the graph representing material B is explained by the fact that this material contains considerably more manganese than the other steels of the series. These graphs would, if assembled on one sheet, be located approximately in the order of their tensile strengths.

SUMMARY

Graphs of endurance test results on either logarithmic or semi-logarithmic paper show no evidence of abrupt change of direction throughout the cycle range investigated. Results of all the tests give cumulative evidence that the idealized stress-cycle graphs on either logarithmic or semi-logarithmic paper should be represented by nearly straight lines.

Semi-logarithmic plotting was finally adopted, since it best represents stress differences, especially at the higher stresses. Semi-logarithmic plotting, moreover, would best reveal any slight downward-convex curvature that may possibly appear as a result of further experiment. In the present state of the evidence the idealized graphs have been represented on semi-logarithmic paper as straight lines.

The angles of slope of these graphs are such as to indicate that for this type of endurance test the drop in endurance stress with increase in number of endurance cycles is not nearly so rapid as has been previously supposed. The average drop with a thousand-fold increase in endurance cycles is about 15 per cent.

The endurance stress for 100,000,000 endurance cycles bears no definite relation to the corresponding proportional limits. The ratio is higher in annealed material than in quenched and tempered material. In ingot iron and annealed mild steels of lower carbon content, the endurance stress for 100,000,000 endurance cycles is above the proportional limit. In quenched and tempered steels, it is often less than half the proportional limit.

The endurance stresses for 100,000,000 endurance cycles have been found to bear a surprisingly uniform relation to the corresponding ultimate tensile stresses. In the many kinds of material investigated, this ratio varies from about 0.35 to 0.54, the highest value being found in ingot iron. The average ratio is 0.44 ± 0.033 .

The ratio of endurance stress to Brinell hardness, and the ratio of endurance stress to maximum torsional stress, are nearly as uniform as the ratio of endurance stress to ultimate tensile stress.

Until further evidence accumulates, it may be stated that chemical composition has little effect on endurance properties other than its effect on ultimate tensile stress.

A comparison of impact test results with the results of endurance tests has shown no definite relationship. Additional experiments, however, are being made, the results of which will be discussed in the future.

The Volume of Air Required in Air Drying

Problems Which Confront the Average Engineer in Attempting to Find the Volume of Air Required in Air Drying—Calculation From Wet Bulb Temperatures and Psychrometric Tables—Charts for 100, 85, and 70 per Cent Ultimate Humidity

By C. T. MITCHELL

Mechanical Division, The J. G. White Engineering Corporation

IN AIR-DRYING operations it is convenient and often essential to know what quantity of air, under certain conditions of temperature and humidity, is necessary in order to evaporate a given amount of moisture. This problem is a comparatively simple one to a specialist in air conditioning, but, on account of the many variables involved, is apt to be a perplexing one to the average engineer, who has not the time to devote to its solution in detail. Not finding tables or formulas at hand with the required information, he resorts to approximation. If he has a well-developed sense of proportion, he may make some very good guesses. On the other hand he may not. The writer has never seen any tables or charts published giving the above-mentioned information directly, and has consequently thought it worth while to prepare the accompanying charts, in the hope that some one may find them **worthy of insertion in his scrap book.**

FACTORS AFFECTING ATMOSPHERIC EVAPORATION

It is perhaps not generally realized, at least by those with a non-technical education, that atmospheric evaporation, such as goes on around us every day, consists of two distinct operations. First, there must be heat by which to vaporize the water. Next there must be an abundance of air present to associate with the vapor and carry it away. The drier the air the more water vapor it will be able to carry and the quicker will be the evaporation.

The humidity of the air in drying operations under atmospheric conditions is consequently quite as important as the temperature. It is easy to imagine that when air is highly saturated an enormous quantity of it will be required to absorb a small amount of moisture. This fact seems almost too simple to bear repetition, and yet the writer has seen the doors of dry rooms closed in order "to keep the heat in," when there was no means of circulation except through the door itself.

Since the pressure is constant in most air-drying operations, the present article deals with only two variable factors, temperature and humidity, the air being taken at constant pressure, and approximately 30 in. barometer. Most drying is done under these conditions, and a vast proportion of it, fortunately, is possible without technical guidance and with a fair amount of efficiency. Yet the average laundress would no doubt be astonished to hear that several thousand pounds of atmosphere must come in contact with the clothes hanging on her lines before they are dry. We venture to say also that many engaged in drying material of a much more refractory nature than clothes would be more or less astonished were they able to visualize the enormous quantities of air which must pass through their dry rooms, unassisted save by natural circulation. Some of

them might even be inclined to doubt the figures as given in the charts. For their benefit an explanation will be given as to how the curves were plotted.

COOLING OF AIR DURING EVAPORATION

The problem is as follows: A certain volume of air, say a cubic foot, is brought into contact with moist material and permitted to remain there until saturated. If we know the weight of moisture in the unit of air before evaporation and subtract it from the weight of moisture in the air after evaporation, then divide the result into the number of pounds of moisture to be evaporated, it is evident that we will arrive at the number of cubic feet of air necessary, at the initial temperature and humidity. The problem is complicated, however, by the fact that the temperature of the air drops during evaporation and that each degree drop lowers the saturation point. What temperature will it finally arrive at? Also, when the air cools, it shrinks slightly in volume, but this is offset again to a certain extent by an increase in the volume due to the addition of the vapor to the original. Since we know that the latent heat of evaporation of the moisture to be removed has been borrowed from the cubic foot of air itself, we might balance these two heat quantities and arrive at the result in this way. Since the latent heat varies with the temperature and there are several other variables in the problem, with no possibility of establishing sufficient equations for a solution, we find that it would be necessary to work out the result by trial. As this would be very cumbersome and open to inaccuracies and arguments as to the correctness of the values used for the specific heat of moist air, we search for another method of solution, and find one ready made for us—namely, the tabulations of the wet and dry bulb thermometer readings as embodied in Carrier's psychrometric chart. The wet bulb temperature has been defined as the temperature to which the evaporation of water from a wet cloth cools the mercury bulb of a thermometer when slung through the air. The following definition seems more expressive if less noncommittal, however: The wet bulb temperature is the approximate ultimate temperature to which air may be cooled by the process of evaporation. This brings out the distinction between the wet bulb temperature and the dew point. The dew point is the temperature at which air reaches the saturation point when cooled by external means. The two are different and the explanation may be illustrated as follows.

DISTINCTION BETWEEN WET BULB TEMPERATURE AND DEW POINT

Imagine two sealed boxes, each box containing 1 cu.ft. of air, the temperature and humidity of the air in both boxes to be the same. The sides of the boxes

must be perfectly insulated against heat interchange with the outside air, and each box must be capable of expanding or contracting with change of temperature, so as to keep the barometric pressure constant inside the box. In one box is a brine coil through which brine of a gradually lowering temperature is circulated. The air in the box is thus slowly cooled to the point where moisture begins to deposit on the coil. The circulation of brine is now continued at constant temperature until all the air in the box is at the same temperature as the brine. This temperature is the dew point of the original air. Into the other box we inject a tiny spray of water, and by means of a small pump located inside the box itself, we continue the spray effect, using the same water over and over again until the air has become saturated and will absorb no more. To avoid criticism we will assume that the temperature of the water at the beginning of the experiment is the same as the wet bulb temperature of the air. The temperature of the air in this box is now found to correspond to the wet bulb temperature of the air before injection of water. It is evident that the temperature in the box with the brine coil will be the lower of the two, because the brine has been continually removing heat, while no heat has been added or taken away from the other box. This may be also proved in another way: The atmosphere in the box with the brine coil has neither lost nor acquired moisture, while in the other box a definite amount of moisture has been absorbed. Since the

FIG. 1. VOLUME OF AIR REQUIRED IN AIR DRYING, ULTIMATE HUMIDITY OF AIR, 100 PER CENT

atmosphere in both boxes is in a saturated condition at the conclusion of the experiment, we know that the atmosphere containing the most moisture must be at the higher temperature, other things being equal.

Experiments of this kind would be difficult to carry out in practice, except in a laboratory. The wet bulb, or sling psychrometer, is a simple instrument, however, and gives readings which approximate very closely to the temperature in the box with the water spray. By

FIG. 2. VOLUMES OF AIR REQUIRED IN AIR DRYING, ULTIMATE HUMIDITY OF AIR, 85 PER CENT

passing the wet, muslin-covered bulb rapidly through the air, the utmost cooling possible by evaporation is accomplished, which means that the atmosphere adjacent to the bulb is in a saturated condition.

CALCULATION OF VOLUME OF AIR REQUIRED

To return now to the problem: A unit volume of air (surrounded by other air subject to the same conditions and therefore not affected by heat interchange) comes in contact with moisture in a drying room, absorbs all it can hold, in the case of 100 per cent evaporation, and passes out. Its exit temperature is evidently the wet bulb temperature and may be read at a glance from the psychrometer chart or from tables, provided the original temperature and humidity of the air are known. Suppose, for instance, that the initial temperature of the air is 90 deg. F. and that it carries 50 per cent humidity. The wet bulb temperature is 75 deg. Consequently the air will pass out of the dry room, if saturated, at 75 deg. A cubic foot of air in this condition holds 0.001346 lb. of water. Before entering the dry room a cubic foot of the same air contained 0.001066 lb. of water. We cannot subtract one directly from the other in order to find the net moisture acquired, because the volume has changed. We must therefore start with more than a cubic foot, so that when we reduce the temperature to 75 deg. (without adding moisture) we shall have exactly a cubic foot. This is very easily done by means of the ratio of absolute temperature; since no condensation occurs in the process of cooling, the initial moisture in the air is in a superheated condition and follows the same law of expansion and contraction as the air itself. We have another slight correction to make, since the outgoing air has taken on moisture and therefore added to its volume. Looking up the vapor pressure of saturated steam at 75 deg. F. we find it to be 0.4288 lb. absolute. Now the total pressure of the air and steam combined is 14.7 lb., since we have assumed this condition at the start. The difference is

$$14.7 - 0.4288 = 14.2712$$

If the air had been dry at the start, the correction in volume would be $\frac{14.27}{14.7}$. But it already contains a

considerable amount of moisture, and a mental calculation shows us that the acquired moisture in the outgoing air is only about one-fifth of the total ($0.001346 - 0.001066 = 0.00028$, which is approximately one-fifth of 0.001346). Therefore the correction in volume is as follows:

$$\frac{14.7 - \frac{0.4288}{5}}{14.7} = \frac{14.614}{14.7}$$

This correction happens to be almost negligible, in this particular case. We can now write out the result,

$$0.001346 - \left[0.001066 \times \frac{460 + 90}{460 + 75} \times \frac{14.614}{14.7} \right] = 0.000258 \text{ lb.}$$

of moisture acquired per cubic foot of outgoing air. Dividing into 1, we find that for every pound of moisture evaporated by air at 90 deg. 50 per cent humidity, 3,876 cu.ft. of saturated air at 75 deg. must pass out of the dry room. As it is more convenient to express this in terms of the entering air, we apply the same correction as above, and obtain the result which is incorporated in the accompanying charts—namely, about 4,000 cu.ft.

PREPARATION OF THE CURVES

The curves in Figs. 1, 2 and 3 were all plotted in this manner. Calculations were all made and checked on the slide rule, as greater accuracy than this would seem to be superfluous. In fact, an accuracy of 90 per cent (assuming 100 per cent accuracy for the wet bulb records themselves) is probably all that could possibly be desired by anybody, since these curves are in no sense a contribution to scientific knowledge, but merely

FIG. 3. VOLUMES OF AIR REQUIRED IN AIR DRYING, ULTIMATE HUMIDITY OF AIR, 70 PER CENT

an aid to the engineer or plant manager in working out problems. The inevitable irregularities in the curves were smoothed out in tracing, but in no case to affect the accuracy of the reading more than 10 per cent. There are certain conditions of initial high temperature and high humidity where a slight error in the temperature reading would make a very large error in the quantity of air. In these cases the curve was either omitted, or, where the result was reasonably certain, drawn with dotted lines. Exit temperatures of the air have been shown in small figures, at regular intervals along the curves. These temperatures could be expressed by a series of curves running counter to the others, but it was felt that this would unnecessarily crowd the diagram. Three conditions of ultimate humidity, 100, 85 and 70 per cent, have been considered in Figs. 1, 2 and 3 respectively. The calculations are the same for all three, since the exit temperature of air at a given humidity may be read from the psychrometric diagram just as readily as the wet bulb temperatures.

DEDUCTIONS FROM CURVES

It is thought the curves will be interesting to many who are not immediately concerned with their practical value. The most outstanding thing which they illustrate is the importance of low initial humidity for efficiency in drying. For instance, it is seen that a given volume of air at 50 deg. with 10 per cent humidity will absorb as much moisture as the same volume of air at 100 deg. with 50 per cent humidity. By the flattening of the curves, as the initial temperatures pass beyond 110 deg., we are led to assume, also, that further increases in temperature are not attended with proportionate increases in efficiency, wholly outside of the difficulties and expense which high initial temperatures entail.

CONFIRMATION OF USE OF WET BULB TEMPERATURE

In conclusion, those who are skeptical as to the use of the wet bulb temperature as the basis of these calculations may check the results independently of the psychrometric diagram, as follows: Taking the same example we used before, which will serve as well as any other, let

H = latent heat of steam at 75 deg. F. = 1049.46.

p = pounds of water evaporated = 0.000258.

S = specific heat of air at 90 deg., 50 per cent humidity = say 0.245.

w = weight of a cubic foot of same air at 75 deg. F. = 0.073.

t = drop in temperature of the air due to evaporation.

Now, since no heat has been added or taken away, the following equation is true:

$$Hp = S \frac{14.6}{14.7} wt$$

The slight correction to the quantity w is necessary since we are borrowing heat units from the air before it has taken on its quota of moisture and become an exact cubic foot.

Substituting the values and solving for t , we obtain

$$t = \frac{1049.46 \times 0.000258}{0.245 \times \frac{14.6}{14.7} \times 0.073} = 15.2 \text{ deg.}$$

which checks as closely as could be expected with the 15 deg. drop registered by the wet bulb.

New York City.

Importance of the Olefine Gases and Their Derivatives

V—Ethylene Chlorhydrin and Ethylene Oxide*

Problems in the Manufacture of Ethylene Chlorhydrin From Ethylene and Hypochlorous Acid—
Properties—Examples of Chemical Reactivity—Production and Characteristics
of Ethylene Oxide—Other Derivatives of Ethylene Chlorhydrin

BY G. O. CURME, JR., AND C. O. YOUNG

THE two chemical derivatives of ethylene which have shown the greatest promise of winning the recognition of the industrial chemist within recent years are those which form the subject of this paper—namely, ethylene chlorhydrin and ethylene oxide. The latter being related to the former as a direct derivative formed by a simple process, they are very similar indeed in their chemical reactivity and constitute together a supplementing pair of reagents, which are characterized by their intensity of reaction and the valuable nature of the products which they may yield. To a student of the development of our organic chemical industry the position of these reagents today seems very similar to that of formaldehyde in the year 1893. At that time formaldehyde was first announced to the industrialists as available in commercial quantities, after having been known to laboratory investigators for many years. The history of its rapid increase in value to the industry needs no recounting.

Today ethylene chlorhydrin, having passed through a difficult period of factory experimentation, has emerged in a position such that it is now capable of production on any desired commercial scale, and at a commercial price. That it is destined to find a large application in synthetic chemistry is assured from the achievements already to its credit.

PREPARATION OF ETHYLENE CHLORHYDRIN

Ethylene chlorhydrin, ($\text{ClCH}_2\text{CH}_2\text{OH}$), which has also been known as β -chlor-ethyl alcohol and glycol chlorhydrin, was first described by Wurtz¹ in 1859. Wurtz prepared it from the already known ethylene glycol by addition of hydrochloric acid. A few years later Carius² described the more direct synthesis by the addition of hypochlorous acid to ethylene, which was the basic reaction on which the present commercial processes have been founded. Carius prepared the hypochlorous acid by the action of mercuric oxide on chlorine, which naturally would not lend itself well to large-scale commercial operation on grounds of expense. Since this original discovery that hypochlorous acid in dilute aqueous solution does add to ethylene with formation of ethylene chlorhydrin, a great deal of work has been done on other methods of generating hypochlorous acid so that it might suitably be added to the gaseous ethylene.

A contribution from the Mellon Institute of Industrial Research of the University of Pittsburgh.

*This article, the last of a series of five, treats of the technical significance of two related ethylene derivatives which are just commencing to be recognized by industrial chemists for their valuable chemical reactivity and which are now available commercially through the development work carried out by the Carbide & Carbon Chemicals Corporation. Parts I, II, III and IV were published Nov. 16, p. 907, Nov. 23, p. 957, Nov. 30, p. 999, and Dec. 7, p. 1049, respectively.

²Carius, *Ann.*, vol. 126, p. 197 (1863).

Lauch,³ Bamberger,⁴ Schweitzer⁵ and others worked upon the idea of adding a weak acid to a solution of liquid bleach ($\text{NaOCl} + \text{NaCl}$) with the idea of liberating the free hypochlorous acid in the presence of ethylene but not the stronger hydrochloric acid. Among the acids used were boric acid, carbonic acid and sodium bicarbonate. These procedures were an improvement in the arts and to the writers' knowledge can be used to give consistent yields of ethylene chlorhydrin, although expensive in operation. A patent on the process of adding an excess of sodium bicarbonate to an alkaline solution of sodium hypochlorite in the presence of ethylene was granted to Walker⁶ in 1910. McElroy⁷ has taken out a series of patents on the production of ethylene chlorhydrin by the action of chlorine on ethylene and oil gas in the presence of steam, and in an electrolytic cell, although with results that do not seem as successful as those obtained by earlier processes. According to Norris⁸ the Badische Anilin und Soda Fabrik has used a process which consisted in bubbling a mixture of ethylene and carbon dioxide through a suspension of bleaching powder contained in a lead vessel. It was by this process that the chlorhydrin used for mustard gas production by the Germans during the great war was largely obtained. Gomberg⁹ found that concentrations of 5 to 8 per cent of ethylene chlorhydrin could be obtained by passing ethylene and chlorine into cooled water, but stated that above that concentration largely ethylene dichloride was formed by further reaction, owing to the action of the accumulated hydrochloric acid in solution. Brooks,¹⁰ in a recent critical survey of the manufacture of chlorhydrins, describes a similar process of his own, wherein the liberated hydrochloric acid is taken up by added salts of weak acids, such as borax or sodium bicarbonate. In this case also the ethylene dichloride reaction seems to intervene after a concentration of 5 to 6 per cent of ethylene chlorhydrin has been built up. In a process developed by the writers, which has been made the subject of a pending patent application, it has been found possible by use of a recirculation system to build up a concentration of 10 to 12 per cent of ethylene chlorhydrin with no appreciable ethylene dichloride formation, at the same time avoiding the necessity of contaminating the system with foreign salts or gaseous materials. Ethylene chlorhydrin has been in limited commercial

use in Germany for some time and recently has been advertised for sale in this country as well as in France.

The pure material produced by any of the above processes is a colorless liquid of faint ethereal odor. It has a boiling point of 128 deg. C. at 740 mm. and a density of $D^{16} = 1.2130$. It is miscible with water in all proportions. As is characteristic of the alcohols, ethylene chlorhydrin also forms a constant boiling mixture. This mixture has been found to contain 42.3 per cent chlorhydrin and 57.7 per cent water by weight and boils at 96.0 deg. C. at 740 mm. It has the density $D^{16} = 1.0970$. By suitable rectification this constant boiling mixture can be separated from the more dilute aqueous solutions in which it is first produced and as such can best be brought upon the market. The process of concentration to the absolute or 100 per cent chlorhydrin is not exceptionally difficult, but adds materially to the cost of the product, as is the case with the alcohols.

The anhydrous ethylene chlorhydrin is a remarkable solvent in that it possesses the valuable solvent characteristics of both the alcohols and the organic chlorides. For this reason it is miscible with water as well as most organic liquids, and dissolves materials of all classes from inorganic salts to the cellulose esters. Patents on its use as a solvent for cellulose acetate have been taken out.¹¹ It has the disadvantage, however, that it is readily hydrolyzed, which limits its use as a solvent.

CHEMICAL REACTIVITY

The chief value of the ethylene chlorhydrin, as stated above, is its great chemical reactivity. Possessing as it does a two-membered carbon chain with a reactive, but different, radical on each of the two ends, it offers a bivalent ethylene radical which can be used for an unlimited number of syntheses. To renew the analogy with formaldehyde, its great advantage in synthetic work is that it offers a bivalent radical, namely, methylene ($-\text{CH}_2-$) which can join with two different groups and bind together like or unlike radicals into a highly complex molecule. With ethylene chlorhydrin the same is the case, except that the uniting bivalent radical in this case is different, namely, ethylene ($-\text{CH}_2\text{CH}_2-$) and therefore the series of derivatives will be of a different but no less valuable class.

One particular case where the value of ethylene chlorhydrin has been commercially developed is in the synthesis of indigo, as described in the patent of the Badische Anilin und Soda Fabrik.¹² In this case the chlorhydrin unites directly with aniline to give hydroxyethyl aniline, and this material in turn is condensed by a simple caustic fusion to a material that may readily be oxidized to indigo. This process is reported to be in extensive use in Germany and in Switzerland today, and is stated to have material advantages over the other syntheses. It was the chlorhydrin originally intended for this synthesis that was used to produce the first mustard gas. The same mustard gas (β, β' -dichlorethyl sulphide) synthesis is again characteristic of the bivalent reactivity of ethylene chlorhydrin.¹³ Here ethylene chlorhydrin is treated with sodium sulphide, giving thiodiglycol as a first product of reaction. This substance then forms mustard gas directly by addition of strong hydrochloric acid solution.¹⁴ Again, phenyl ethyl alcohol is produced from brombenzene and ethyl-

ene chlorhydrin by the Grignard reaction,¹⁵ and novocain¹⁶ through the reaction of ethylene chlorhydrin and amino benzoic esters. These examples serve only as an indication of the variety and scope of reactions in which a bivalent radical, capable of selective addition on either end, can accomplish simplified and elegant reactions in the field of commercial organic synthesis.

PRODUCTION OF ETHYLENE OXIDE

From ethylene chlorhydrin solutions by action of strong caustic alkali, a rather unusual reaction occurs in which hydrochloric acid is split off from the chlorhydrin and ethylene oxide is formed directly. This reaction was first described by Wurtz¹⁷ in 1859. In many repetitions of this process by successive investigators no essential improvements have been worked out.

The ethylene oxide (CH_2)₂O prepared in this manner is a colorless liquid with a characteristic pungent odor, similar to that of pure ethylene. It is quite volatile, boiling at 12.5 deg. C. at 746 mm. It has the density $D^{16} = 0.8966$. It is miscible with water in all proportions. On account of its low boiling point, this material must be handled as a gas in any commercial work, but when liquefied in steel cylinders it is easily transported and very easily applied in any reaction.

Forming as it does a three-membered ring, ethylene oxide is characterized by its great chemical reactivity and undergoes practically the same reactions as does the chlorhydrin. In some cases it reacts even more easily. Since it can very readily be prepared in the anhydrous condition and also contains no chlorine, it is preferable in many reactions on this account. The two reagents supplement each other handsomely.

OTHER DERIVATIVES OF ETHYLENE CHLORHYDRIN

Other direct derivatives of ethylene chlorhydrin also appear to have commercial value. Of these ethylene glycol ($\text{CH}_2\text{OH}.\text{CH}_2\text{OH}$) has already attracted considerable interest, being produced readily by the action of sodium bicarbonate on chlorhydrin solutions.¹⁸ This material has already been used in many applications where it has been shown that it can replace glycerine to good advantage, as in manufacture of explosives,¹⁹ in moistening tobacco, in cosmetics, extracts and in other such uses.

Glycol monacetate ($\text{CH}_2\text{OH}.\text{CH}_2\text{OCOCH}_3$) is another direct derivative, and has attracted some attention as a solvent. In particular it is claimed to aid in dyeing artificial silk from cellulose acetate.²⁰ Glycol diacetate ($\text{CH}_2\text{OCOCH}_3$)₂ is another derivative, and as a high boiling solvent (b.p. 186 deg. C.) deserves some attention.

This list of higher syntheses involving chlorhydrin and its derivatives as well as that of its direct derivatives might well be continued to much greater length, but such a detailed review is beyond the scope of this paper. It is hoped, however, that it has been possible in the relatively few instances cited to show that, along with the other technical products of the olefine gases, ethylene chlorhydrin offers a new field of development to the organic chemical industry.

¹⁴This synthesis was not adopted by the Allied Powers to produce the mustard gas for the past war, as no commercial chlorhydrin process was at that time satisfactorily developed. As an operating process it is, however, the safest and yields the highest grade of material.

The Electrolytic Oxidation of HCl to Perchloric Acid*

Earlier Methods for the Preparation of Perchloric Acid—Apparatus and Procedure for Studying Electrolytic Oxidation of Hydrochloric Acid—Experimental Data—Type of Cell Developed From Results of Preliminary Work—Bibliography

By H. M. GOODWIN† AND E. C. WALKER, 3D‡

THE purpose of the following investigation was to determine the best conditions under which hydrochloric acid could be electrolytically oxidized to perchloric acid, and to devise a cell for carrying out the process on a practical scale. That perchloric acid can be formed by the electrolysis of hydrochloric acid has long been known, the fact having been noted by Count Stadion¹ in 1816. In 1898 Haber² investigated the electrolysis of hydrochloric acid solutions and stated that when dilute solutions are electrolyzed, small amounts of perchloric acid are formed.

Up to the time this investigation was undertaken, in 1916, perchloric acid was made by one of the following methods:

1. By heating a concentrated solution of chloric acid. As pure chloric acid is not readily prepared and the yield of perchloric acid is low, this method is of little practical value.³

2. By the action of fluosilicic acid on potassium perchlorate and subsequent distillation of the filtrate of dilute perchloric acid. This method is obviously difficult and of theoretical interest only.⁴

3. By the action of sulphuric acid on barium perchlorate with subsequent concentration and distillation. The chief objection is that the barium salt is expensive.⁵

4. By steam distillation under reduced pressure of a mixture of potassium perchlorate and sulphuric acid. A good yield is claimed by this method.⁶

5. By the action of concentrated hydrochloric acid on sodium perchlorate and concentration of the filtrate until excess of hydrochloric acid is driven off.⁷ Mathers⁸ states that this method yields 95 per cent of the theoretical acid, and with cheap sodium perchlorate would seem to be the best method thus far proposed.

6. By the action of aqua regia on ammonium perchlorate. This method is stated by Willard⁹ to give good results, but owing to the explosive nature of ammonium perchlorate is restricted in its use.

All of these methods, except the first, presuppose the formation of perchlorates and the subsequent liberation

of the free acid. In the following experiments the attempt was made to form the acid directly from hydrochloric acid without the intermediate formation of one of its salts.

In oxidizing the chlorine ion to the perchlorate ion it must of course pass through the chlorous and chloric stages. The theory of the formation of the chloric ion and chlorates and the best conditions for effecting this electrolytically are well known. The mechanism of the further electrolytic oxidation of the chlorate to the perchlorate ion was studied by Oechsli¹⁰ in 1903 and more recently in a comprehensive article by Bennett and Mack¹¹ in 1916. The former holds that the perchlorate ion is formed only under conditions of sufficiently high overvoltage to permit the preferential discharge of chlorate ions, which then by secondary reactions with the water form chloric and perchloric acid. Bennett and Mack on the other hand maintain that experimental evidence bears out the view that perchlorate formation is due to the direct oxidation of the chlorate ion by nascent oxygen present in a state of high concentration in an anode at which there exists a high oxygen overvoltage. For a detailed discussion of these two theories Bennett and Mack's paper should be consulted.

Whatever the mechanism of the process may be, the facts seem well established that chlorate ions are most readily oxidized to perchlorate ions in acid solution, at low temperature, high current density and at electrodes, like smooth platinum, which give a high oxygen overvoltage. Chlorate ions, on the other hand, are more efficiently formed at higher temperatures, lower current densities and in concentrated solutions.

APPARATUS AND PROCEDURE

To ascertain the extent to which hydrochloric acid can be oxidized to perchloric acid under varying conditions, a large number of experiments were first carried out in the apparatus described below. This consisted of two concentric cylinders—the inner, a platinum tube 22 cm. long and 0.55 cm. diameter, which served as anode, and the outer of copper 20 cm. long and 6 cm. diameter, which served as cathode. The platinum tube passed through the center of a rubber stopper large enough to close the lower end of the copper cylinder. The stopper and upper parts of the copper tube not in contact with electrolyte were covered with paraffine to prevent corrosion by the action of free chlorine.

The temperature of the cell was regulated by passing a current of water through the anode and up and around the outer copper cylinder, the whole cell being placed in a beaker.

In series with the cell were an ammeter, a rheostat

and a copper coulometer. The voltage across the cell terminals was recorded at intervals by a voltmeter.

Preliminary experiments showed that the amount of perchloric acid produced by the electrolysis of hydrochloric acid depended upon: (1) Duration of electrolysis. (2) Current density on the anode. (3) Concentration of HCl. (4) Temperature of electrolyzing cell. (5) Anode material.

The usual procedure was therefore to keep four of these factors constant and vary the fifth over a sufficient range. For example: all the above conditions were kept constant except the duration of electrolysis. This factor was varied so that data were obtained to determine the products of electrolysis from the time when approximately 3 ampere-hours had passed, to the time when all the available acid had been converted to perchloric acid. Thus, successive portions of 150 c.c. of HCl were electrolyzed at constant current density, acid concentration, temperature and anode material at different values of ampere-hours passed until complete data had been obtained for these conditions.

The next step was to change the current density and make another series of electrolyses, keeping this new value of current density constant with the other factors, while a new set of data was being obtained at various ampere-hours.

When the current density had been varied over a sufficient range, the concentration of the acid was changed and the above-described system of runs was repeated with varying current density and ampere-hours for this new concentration of acid.

At the completion of the electrolysis, the electrolyte was removed from the cell and shaken with mercury to remove the free chlorine. After filtering out the mercurous chloride, the filtrate was analyzed for chloride, chlorate and perchlorate. Three aliquot portions were pipetted off into Erlenmeyer flasks. The first was titrated with N/10 NaOH, using phenolphthalein, to give the total acid. The second portion was acidified with HNO_3 and titrated for chloride by adding an excess of AgNO_3 , boiling to coagulate the AgCl and titrating the excess of silver nitrate with ammonium sulphocyanate, using ferric-ammonium alum as an indicator. The third portion was acidified with dilute nitric acid and an excess of a 10 per cent solution of ferrous sulphate added to reduce the chloric acid. After boiling for 10 minutes an excess of silver nitrate was added and the chloride-chlorate chlorine determined as

before. The perchloric acid was thus determined by difference.

The results obtained from a number of typical runs made with this apparatus are shown in the accompanying table. The volume of solution electrolyzed in each case was 150 c.c.

A study of the figures in the table shows:

1. That in dilute solutions, N/10, as much as 50 per cent of the original acid may be converted into perchloric acid, the larger part of the remaining acid being lost as chlorine.

2. That with increasing concentration, the per cent which can be thus converted rapidly diminishes, decreasing to 10 per cent in half normal solution. The loss as chlorine rapidly increases (approaching 100 per cent for concentrations over N/1).

3. The per cent of chloric acid, on the other hand, in the electrolyzed liquor increases with increasing initial concentration.

4. Increasing the current density 100 per cent (from 0.1 to 0.2 amp. per square centimeter), increases the percentage conversion to perchloric acid slightly (from 41.6 to 44 per cent), while the percentage energy increase is much greater (25.8 to 37.9 watt-hours).

5. Increasing the temperature from 20 to 40 deg. tends to decrease the perchloric acid yield, but to increase that of chloric acid present. The energy consumption is at the same time decreased.

With the above results as a guide, the design of a new type of cell was next undertaken in which the oxidation of hydrochloric acid to perchloric could be carried out continuously.

FINAL FORM OF CELL

Without entering into the details of the construction and operation of a number of forms of apparatus which developed difficulties for long-continued operation, the final form only, which gave excellent service, will be here described.

The form of the cell was that of a long, narrow rectangular trough flared at the top. Its dimensions were 18 in. long by 6 in. deep by 1 in. wide (45.7 x 15.2 x 2.5 cm.). It was hammered out of a sheet of silver 30 x 14 x 0.005 in. thick (76 x 35.5 x 0.013 cm.), and was without any seams. This trough, which served as the cathode, was reinforced and supported in a copper mesh frame (two wires to the inch of No. 16 B. & S. gage (0.13 cm.), to which it was soldered at several

points. A silver outlet tube was welded in the bottom of the cell by silver solder. The cell was immersed in a water bath, a strong spray of cooling water being continuously sprayed over both sides of the cell from perforated pipes placed in the bath. By regulating the rate of flow of the spray, the temperature of the cell could be adjusted within wide limits. Sheet silver was finally chosen for the cell, after copper, iron, nickel, Monel, lead and silver-plated copper had been tried out, and all found to develop difficulties in long-continued electrolysis from the corrosive action of the chlorine.

In the endeavor to find a protective coating which would resist the action of chlorine outside the cell, paraffine, ceresin, shellac, asphalt, asphalt paint and a solution of Grade A Bakelite in amyl acetate were used. Of these the last, when properly applied, dried and baked at a temperature not exceeding 150 deg. C., proved very satisfactory.

The anode was of sheet platinum, approximately 5 x 16 in. (12.7 x 41 cm.) in area, and 0.0015 in. (0.0038 cm.) thick, suspended in the center of the cell from a heavy copper rod to which it was clamped. All copper parts and contacts were protected by Bakelite. The anode was held down in place by a glass rod and glass balls attached to the lower edge.

In a continuous run the hydrochloric acid flowed into the cell from a reservoir containing a stock solution and the electrolyzed liquor ran off into two 12-in. fused silica Vitreosil evaporating dishes arranged in cascade in which the perchloric acid was concentrated. The flow of the liquid was controlled by an automatic electric regulator, perfected by E. C. Walker and F. W. Hall. The evaporation was continued until a 60 per cent solution of perchloric acid which boils under atmospheric pressure at 160 deg. C. was obtained. For use in analytical work this solution was distilled; the product thus obtained contained only a slight impurity of silica accompanied by alumina which probably came from the evaporating dishes.

With a single cell of this type about 50 lb. of 50 per cent pure perchloric acid was made during the course of the investigation. The following data taken on one series of experiments illustrate the extent to which the original hydrochloric acid could be converted to perchloric acid:

Initial concentration of hydrochloric acid, 0.5 N.
Average current, 150 amp.
Average voltage, 8 volts.
Average current density (anodic), 0.16 amp. per square centimeter.
Average rate of flow of liquor through cell, 25 to 30 liters per hour.
Average temperature, 18 deg. C.

Run 1.

Concentration of HCl at end, 0.0179 N.
Concentration of HClO₃ at end, 0.0255 N.
Concentration of HClO₄ at end, 0.0738 N.

The product from this contained too great a percentage of chloric acid. It was therefore brought up to 0.5 normal by the addition of hydrochloric acid and again electrolyzed in the cell with the following results:

Run 2.

Concentration of HCl at end, 0.171 N.
Concentration of HClO₃ at end, 0.0089 N.
Concentration of HClO₄ at end, 0.2015 N.

This solution contained 20 g. of perchloric acid per liter. By again bringing up the acidity and electro-

lyzing, a solution of the following composition was obtained:

Run 3.

Concentration of HCl at end, 0.01117 N.
Concentration of HClO₃ at end, 0.0078 N.
Concentration of HClO₄ at end, 0.286 N.

In the first and worst case in which the original acid was subjected to electrolysis by passing once through the single cell, a yield of approximately 800 g. of 60 per cent acid per 24 hours at an expenditure of 28,800 watt-hours, or about 26 watt-hours per gram of acid (60 per cent), was obtained.

There is no doubt that better results could be obtained by the use of two cells, in the first of which the best conditions for the production of chloric acid were maintained—i.e., fairly strong acid, high temperature and medium density—while in the second the products of the first cell would be electrolyzed under the most favorable conditions for the oxidation of chloric to perchloric acid—namely, more dilute solution, low temperature and high current density.

The results obtained with our apparatus demonstrated, however, that a high grade of perchloric acid could be produced in quantity by the electrolysis of hydrochloric acid.¹²

In conclusion, it may be of interest to add that with the acid obtained the salts of the following metals were prepared: Strontium, zinc, copper, manganese, nickel, cobalt, iron (ferrous and ferric), tin, bismuth, gold, beryllium and uranium.

These salts are all very soluble in water, and with the exception of the ferrous, nickel, cobalt and zinc salts, are decidedly hygroscopic. The use of perchlorates, especially of the lead salt, for electroplating purposes is well known from the work of Mathers,¹³ as they are very stable and not readily reduced by hydrogen. Ferrous perchlorate is also remarkably stable as regards oxidation.

Material Handling as a Factor in Eliminating Industrial Waste*

By H. V. COES

Manager, Ford, Bacon & Davis. Member A.S.M.E.

MODERN civilization is the direct result of the application of the principles of subdivision of labor. This in turn has resulted in labor-saving inventions, and material-handling devices have played an important part in this development. Yet today, in spite of equipment and methods now available, material is handled constantly in identically the same manner as in the early stages of civilization.

Why is this? In the opinion of the author, it is due to a number of influences, such as: (1) Ignorance of methods and equipment available. (2) Lack of standardization of materials, methods, containers to be handled to permit installation of and economical use of material-handling apparatus. (3) Insufficient comparative economic data. (4) Improper engineering. (5) Poor salesmanship and selling policies. (6) Lack of a central organization to educate the public and to act as a clearing house for economic and technical information.

There has recently been published an Encyclopedia of Material Handling, prepared by recognized authorities. This is a step in the right direction and it should prove of considerable assistance, particularly in eliminating ignorance of methods and equipment.

be an economic one. The question of will it pay should not be begged. Capital has been wasted, pioneers discouraged, the public bewildered because of undertakings not conforming to this test.

Hunt¹ postulates these principles as follows:

1. In handling material, perform only the handling operations that are absolutely necessary.

2. Perform these operations in the way that obtains the lowest cost.

When a simple plan for handling materials has been developed, the financial returns of the installation will, in the absence of labor difficulties, largely determine the wisdom of the installation. It may pay to install apparatus and it may not, according to conditions such as: (a) Constancy or intermittency of the work, (b) character of the operation itself and (c) results of analysis which follows.

A specific example of the saving effected by the introduction of proper methods of handling materials occurred in the case of a certain paper mill. The mill was 60 years old or more, and had grown around itself in a manner that presented a number of problems difficult to solve. After a policy for rehabilitation and extension had been worked out, it was possible to predict future material-handling costs, based upon improvements that would obtain under the rehabilitation plan and application of the proper material-handling equipment to the problems in hand. Table I illustrates the varied

TABLE I. ESTIMATED ANNUAL COST OF PRESENT AND PROPOSED METHODS OF HANDLING MATERIAL IN A CERTAIN PAPER MILL
(Based on Average Quantities Consumed in Year 1919 and 6 Months 1920)

Material	Unit	Average Annual Consumption	Present Cost*		Estimated New Investment	Proposed Cost*		Annual Saving		Equipment Selected
			Unit	Total		Unit	Total	Unit	Total	
Alum.....	Ton	207	\$10.60	\$2,862	\$5,500	\$1.87	\$505	\$8.73	\$2,357	Locomotive crane and power mule
Ash disposal.....	Ton	4,800	2.08	10,000	15,000	0.42	2,000	1.86	8,000	Pneumatic conveyor
Bleach.....	Ton	875	2.80	2,450		2.00	1,750	0.80	700	Locomotive crane and power mule
Clay (china).....	Ton	1,800	4.48	8,064	11,100	1.60	2,880	2.88	5,184	Pneumatic conveyor

				\$99,773	\$114,450		\$38,708		\$61,065	

* The present costs include maintenance and repairs but no fixed charges, or other overhead items. The proposed costs include fixed charges of 20 per cent.

It is a well-recognized fact in industrial-plant operation that the last 20 per cent of operating efficiency is the hardest to obtain, and yet shows the highest return. Thousands of plants in this country do not show an operating efficiency of more than 50 per cent, as compared with those plants that have an operating ratio as high as the present state of the art will permit. There are many reasons for this low operating ratio, but we are concerned only with the losses due to inadequate and inefficient material handling.

Industrial costs are composed of the following factors: (1) Material, (2) production labor, (3) factory burden or overhead, (4) general administration expense and (5) sales expense.

As a usual thing, indirect or non-productive labor is charged out to factory burden. A very large portion of this labor is used in picking up, putting down and transporting material of all kinds. Hence one place to start in reducing factory burden is to reduce waste in labor and expense in this indirect-labor item by substituting adequate and properly adapted material-handling equipment and methods.

The initial test of any method, system or device should

material to be handled, but one would need to know the physical handicaps at the mill to appreciate fully the necessity for and the difficulty of obtaining a right solution of the problem. The preliminary testing and checking of the equipment installed indicate that the savings will be readily obtained and in some cases exceeded as operating proficiency increases.

The public, industrial executives and business men generally are not in possession of sufficient data and economic facts to make them realize the astounding wastes going on all around. Engineers and manufacturers are largely to blame for this. The industrial executive usually knows how much per piece or per unit it costs to produce a given article, but rarely knows what it costs per unit to handle the materials entering into the manufacture of the article itself or the cost of handling the finished article. It is only recently that industrial plants have been designed or laid out on a material-handling basis.

If the manufacturer will get the engineer's point of view and the engineer the manufacturer's, and both will get the economic viewpoint, much good will result, fewer mistakes be made, and society and industry will benefit and prosper.

American Practice in High-Speed Steel Manufacture

Impressions on American Tool Steel Manufacture Received on a Trip of Inspection Covering Several Plants
—Importance of Pure Raw Materials and Metallurgical Control of All
Steps in Process Is Emphasized

BY A. H. D'ARCAMBAL

Metallurgist, Pratt & Whitney Co., Hartford, Conn.

IT MAY be interesting to recount impressions received during a trip of inspection, when eight of the largest tool steel mills in this country were visited, six of which are using the crucible process, the two others melting their high-speed steel in the electric furnace. Several of the mills using the crucible process are now experimenting with the electric furnace method of melting and are obtaining very satisfactory results. The majority of the high-speed steel produced in Europe is crucible melted, although Sweden is manufacturing some electric furnace high-speed steel. One must use just as pure raw materials in electric-furnace practice as it is necessary to use in crucible melting if as high-grade product is expected. Too many mills using electric furnaces have found to their sorrow that they cannot produce a dress suit from a pair of overalls!

The crucible process of melting steel dates back to centuries before Christ, when the Chinese melted steel in crucibles, but it is not the intention to sketch its history, absorbing though that subject may be. The process as used today by most of the large tool steel mills in this country, is as follows:

The base, usually high-grade muck bar,¹ is carefully weighed. Most mills use about 50 lb. to the charge (90 or 100 lb.). Before the war Swedish iron was used to a large extent in this country for the high-speed base, but has recently been difficult to procure. It is the opinion of some American manufacturers, and vigorously disputed by others, that just as good a base is made in this country. One of the mills informed me they were using "Armco" iron for the base, another mill uses a special open-hearth product; but the majority of the plants have found that muck bar, which is almost pure iron, gives the best results.

High-speed scrap is then weighed. This consists of crop ends, bar ends, etc., and usually makes up about 25 per cent of the charge, or 25 lb. In the medicine room, so called, the ferro-alloys are very carefully weighed and placed in pails, which also contain ground brick dust for a fluxing agent. These alloys, such as ferrotungsten, ferrovanadium, ferrochromium, ferromanganese and ferrosilicon, constitute the remaining 25 per cent of the charge. The ferro-alloys are refined in the electric furnace and usually carry the following percentages of the alloying element:

Ferrotungsten.....	75 to 85 per cent tungsten
Ferrovanadium.....	33 to 35 per cent vanadium
Ferrochromium.....	60 to 70 per cent chromium
Ferromanganese.....	75 to 80 per cent manganese
Ferrosilicon.....	48 to 50 per cent silicon

¹Muck bar is genuine wrought iron. Impurities existing in pig iron of special grade are oxidized in a puddling furnace, the pasty iron sponge removed from the furnace in a ball or lump, most of the slag squeezed out, and the rough bloom resulting is rolled directly into a flat bar known as muck bar or puddle bar. Short pieces of muck bar are bundled, reheated to welding heat and rolled one or more times before being marketed in the form of wrought iron bar or pipe.

The proportion of the various alloys added as well as the amount of base and scrap used depends of course on the analysis required. Sometimes it is necessary to add wash metal—a white iron containing 3 to 4 per cent carbon, low in manganese, phosphorus, sulphur and silicon—to raise the carbon, while some mills add a small amount of charcoal. However, carbon is usually controlled by varying the amount of scrap and ferrochromium.

The material is now ready to be charged into crucibles. Crucibles used in America are made of a half-and-half mixture of flake graphite and binding clay. To prevent the graphite in the crucibles dissolving in the steel, they are usually lined with pure clay, lasting for four to six heats, the crucibles then being used for carbon tool steel melting. One mill superintendent states that he does not use this clay lining, but melts high-speed steel in crucibles which have been used for three or four melts of carbon tool steel. He says that steel absorbs only a very little carbon from crucibles which have been used several times.

Ferro-alloys, especially the ferrotungsten, are added near the center of the charge, to insure thorough mixing.

In order to maintain a neutral atmosphere, graphite covers are placed on the crucibles, which are then lowered into the furnace, each "hole" usually providing room for six crucibles. The size of the furnace is expressed by the number of crucibles it contains, such as thirty, thirty-six or forty-two crucible pot furnaces, and would contain, therefore, five, six or seven "holes." These furnaces are of the regenerative type, usually producer gas fired, and will melt the heat in 3½ to 4½ hours. After thorough melting, the heat continues for ½ hour more to permit gases in the molten steel to escape and to bring the steel to the proper casting temperature. This is known as the "killing" process.

Workmen then pull out these pots with large tongs. As it is necessary for them to straddle the open hole while it is at a temperature of around 3,000 deg. F. (1,650 deg. C.), they first wrap their legs and body in burlap, put on heavy shoes with wood and iron soles, drench themselves with cold water and after covering their hands and arms with water-soaked bags are ready for "pulling out." Considering the fact that these crucibles weigh over 100 lb., the job is not an easy one. Steel in these crucibles is then poured into molds or into a large preheated ladle and poured from the latter into the molds. The latter practice is more popular in this country and gives a more uniform analysis, ingot to ingot.

Raw materials used in electric furnace melting depend to a large extent on the available scrap supply. One large producer of electric furnace high-speed steel lists

the following as his raw materials: Muck bar, high-speed scrap, ferrotungsten, ferrochromium, ferrovanadium, ferromanganese, ferrosilicon, wash metal, limestone, lime, fluorspar, silica and ground electrodes. Another well-known manufacturer of high-speed steel states that limestone should never be used in the electric furnace process, for when it is present the heat melts with an oxidizing slag, causing a large loss in alloys. Lime in any form also slows the furnace working, and he states that there is always enough slag left in the furnace to take care of the subsequent heat while melting. He is also of the opinion that it is not necessary to introduce silica into the furnace, and that retort carbon should be used for carburizing in place of ground electrodes, because of the greater purity of the former. Such variations of opinion are given merely as a matter of record, without an attempt to appraise them critically.

Raw materials should be carefully analyzed, for it must be remembered that it is desirable to use just as pure materials in electric furnace melting as it is necessary to use in the crucible process. Anything showing high phosphorus, sulphur, nickel, arsenic, tin, copper, antimony or bismuth should not be used.

USUAL FURNACE OPERATIONS

Furnace operations, as usually carried out, are as follows: Limestone, if used, is first charged on the bottom of the furnace, wash metal next, then muck bar, high-speed scrap and ferrotungsten. The amount of high-speed scrap added usually runs from 30 to 40 per cent, one mill, however, claiming that 70 per cent scrap may be used if properly selected. Electrodes are then lowered, current turned on, and the steel melted, usually under neutral conditions. From 2 to 3 hours is required to bring the charge to a molten condition and approximately 600 kw.-hr. per ton of steel is consumed. A sample for analysis is usually taken at this point.

Slag is now removed and a new slag made of lime, fluorspar and ground electrodes, which maintains a strongly reducing atmosphere as well as a basic reaction toward the metal, thus eliminating oxygen and sulphur. A higher temperature is also usually used during this period to produce the desired chemical reactions. As soon as the bath is thoroughly deoxidized, ferrochromium, ferrotungsten and ferromanganese are added; ferrovanadium, the last alloy added, is usually introduced about 30 to 45 minutes before tapping; a short time before the heat is tapped ferrosilicon is introduced. Silica in small quantities is occasionally used to thin the slag. One large American mill usually makes five analyses during melting, the first being made as soon as the steel is melted, the others taken from time to time after recarburization, depending largely on the slag conditions. The last test is taken shortly before tapping. Five analyses obtained by this mill on one of their heats ran as follows:

	Test No. 1 Per Cent	Test No. 2 Per Cent	Test No. 3 Per Cent	Test No. 4 Per Cent	Test No. 5 Per Cent
Carbon.....	0.43	0.43	0.59	0.59	0.69
Silicon.....					0.29
Manganese.....					0.35
Sulphur.....					Trace
Phosphorus.....					0.019
Tungsten.....	17.29				18.48
Chromium.....	1.90				4.03
Vanadium.....	0.26				.98

When the heat is ready to tap, the slag is grayish white, containing carbide, and producing acetylene gas when thrown in water. One ~~melter~~ thinks that it is

poor practice to work under a carbide slag, as the different ingots poured may show a carbon variation of from 0.05 to 0.15 per cent, depending on the strength of the slag. Other operators say it would be almost an impossibility to eliminate this carbide slag.

Hot electric metal must be "killed" the same as in the crucible process. Correct pouring temperature as well as the condition of the metal is determined by pouring and examining small test ingots, and when the metal is ready the furnace is tilted and the steel poured into a heated ladle. After the hot steel is permitted to stand in the ladle several minutes to allow the trapped non-metallic particles to rise to the surface, the steel is teemed into molds.

Mills making electric-furnace high-speed steel claim the following advantages for their process over the crucible melted product:

1. Any desired temperature can be obtained.
2. More accurate chemical control is possible.
3. Impurities in original raw materials may be eliminated.
4. Better mixing of ingredients is effected.

The advantages of the crucible melted high-speed steel over the electric furnace material are said to be as follows:

1. A more careful examination of base materials is required.
2. Steel is melted in small units.
3. A neutral atmosphere is maintained in the crucible.
4. Unsurpassed ingots are poured by hand.

INGOT PRACTICE

Liquid steel, produced from either of the above processes, is usually cast into split iron molds with solid bottoms. These molds are tapered, and set with the large end up. On top of these molds rest preheated hot tops, or "dozzles," fireclay shells whose outside dimensions are the same as the inside dimensions of the molds. These hot tops act as reservoirs holding molten steel to feed the shrinkage cavities and eliminate piping to a marked degree. Molds are smoked so as to eliminate surface defects on the ingot.

When the ingots have cooled sufficiently, they are stripped from the molds. At this point the practice varies in different mills visited by the writer. The majority immediately anneal the ingots after they are stripped so as to remove all casting strains and to refine the grain as much as possible. Some mills omit this annealing operation, thinking that no benefits are derived.

The ingots are usually sampled for complete analysis, and whether annealed or unannealed are then carefully examined for surface defects. Imperfections are ground or chipped out. A small corner is also usually broken off and the fracture examined.

Ingots are now charged into large heating furnaces, coal or oil fired, and allowed to remain until they have been thoroughly heated to a temperature of approximately 2,100 deg. F. (1,149 deg. C.). They are then hammered by large steam hammers and reduced to billets. The piped end is then cropped off, usually amounting to from 10 to 20 per cent of the weight of the ingot. Billets are again carefully examined for surface defects, usually the entire surface is ground, and a careful examination of a fractured surface is also made. Billets are then charged into reheating furnaces and heated through to the proper temperature for further reduction. In most cases billets are annealed

before being reheated. Finishing to size is done either under hammers or in rolls. A short time ago some interesting experiments were conducted by Messrs. Andrew and Green of the Armstrong-Whitworth Co., England, to ascertain the comparative effect of hammering or rolling on the microstructure of high-speed steel, and no difference was observed, contrary to the widely held opinion that hammering produces a better product than rolling.

Finished bars are usually placed in large tubes, the ends sealed and the tubes then rolled into annealing furnaces, equipped with from four to twelve pyrometers connected to autographic recorders. Furnaces and contents are then brought up to from 1,500 to 1,600 deg. F. (816 to 870 deg. C.), held there for a considerable length of time, then slowly cooled in the furnace, an operation requiring from 2 to 3 days. It will usually produce a Brinell hardness of from 196 to 235, depending on the size of the material being annealed. A few mills use a packing material such as charcoal and ashes in the large tubes, but it is claimed that greater uniformity is obtained without this. A rapid method of annealing high-speed steel is to heat to 1,650 deg. F. (899 deg. C.) cool slowly to 1,300 deg. F. (704 deg. C.) and then air-cool. This will give a Brinell hardness of from 228 to 269, but the method is not used much in this country, as the consumers usually require a softer material.

Annealed bars are then carefully examined with a file for surface defects, their size measured, and both ends nicked and broken to examine the fracture for grain and pipe. Material is also tested for Brinell hardness. Most of the mills follow their steel through the different operations; it is identified with the proper heat number so as to know the analysis and history of the finished stock.

Fig. 1 shows the structure of a high-speed ingot as cast; Fig. 2 the bar produced from that ingot. The cellular structure has been entirely broken up by working, and a fine-grained structure produced with uniform distribution of carbides. A reduction of 85 to 90 per cent is required to break up the cellular structure and diffuse the envelopes. A section of an 8½-in. round high-speed steel bar in the annealed state is shown in Fig. 3. Carbide segregations and the envelope formation present in this annealed material have not been broken up by the manufacturing operations, nor

were they subsequently eliminated in a hardening treatment, although the time and temperature were sufficient to overheat the steel. It is a well-known fact that envelope structures and massive carbide areas will not go into solution upon hardening, and quite often these are the cause of cracking or short life of tools made from them. Large high-speed rounds are never free from these carbide laminations, due to insufficient reduction; forged blanks are therefore finding wide use, as then the steel has been hammered in both directions, and if properly done, this breaks up this segregated structure.

One impression left on the writer after inspecting the various tool steel mills was the influence of the metallurgical department on the quality of the finished product. An accurate chemical control of the raw materials and the finished product is essential if a good, uniform product is to be manufactured. Metallurgical supervision of the casting, cogging and annealing temperatures insures material properly fabricated. In one of the large mills the metallurgical department had full control of all inspection. All of the mills visited had adequate chemical laboratories, and in the majority of cases well-equipped physical testing departments and metallographic laboratories. It was quite noticeable that in some the metallurgical equipment was not used nearly as much as in some of the other mills visited, and I might add that the latter were the plants whose products are ranked among the best in the country.

One often hears it said, mostly by men connected with the tool steel industry, that the analysis of high-speed steel is no indication of its cutting qualities. This statement is true, for in more than one instance two different brands of high-speed steel, with approximately the same analysis, have shown altogether different cutting qualities. This does not mean, however, that the analysis specification is not important and should not be enforced. A large number of rejections have been made because of insufficient carbon, tungsten or vanadium, for such material would surely produce inferior tools. It is, of course, a mistake to purchase high-speed steel under a chemical analysis only, as the microstructure, Brinell hardness and fracture in hardened bar are of such importance that they should be included in the specifications. Yet control of the chemical composition is a step toward uniformity, which is of great importance to any steel product.

Apparatus for Studying Thermal Decomposition of Oil Shales

BY RALPH H. MCKEE AND E. E. LYDER

THE distillation of oil shale may be accomplished in almost any kind of a heating device from which air is excluded and which can be raised to the temperature of decomposition of the pyrobituminous substance. The results obtained usually vary with each method used and the manner in which the distillation is carried out. For a study of the manner in which shales decompose under the influence of heat and the temperature at which they break down to form oils, as well as the effects of steam, gases and various reagents on them it is necessary to have an apparatus in which all of the conditions may be accurately governed and known. These factors may be closely controlled and the quantities measured by means of a small rotary furnace described in this paper. The heating is done by gas, which makes it applicable to almost any laboratory, and the temperature is controlled automatically, as will be indicated later.

The method and apparatus may be used for test work both for oil yield and ammonia, but they are particularly adapted for the study of conditions under which the shale decomposes and the apparatus is on a sufficiently large scale to give results approximately parallel to those obtained in commercial retorting.

Most methods used to date involve starting the shale at relatively low temperature and continually raising the temperature until the oil is completely removed. Recent work has shown that important information may be gained by heating the shale to definite and known temperatures. For instance, it has been shown by the authors² that shale pyrobitumens decompose at quite definite temperatures to form bitumens and that the decomposition takes place over a relatively short range (within 10 deg. C.). Different shales may have different temperature ranges and the determination of these may be important.

¹The term pyrobitumen (after Abraham, "Asphalt and Allied Substances") is used to designate the material in shale which, on destructive distillation, yields bitumens.

²"Thermal Decomposition of Shales," *J. Ind. Eng. Chem.*, vol. 13, p. 613 (1921).

It is also believed that the future economic production of motor fuel from shales will depend upon the efficient cracking of this heavy bitumen first formed. An apparatus and method adopted to the study of the best conditions for the cracking of this heavy bitumen are, accordingly, very desirable.

RETORT

The retort used was of the horizontal rotary type, one which when filled with 1-in.-mesh shale held about 25 lb. The furnace and heating equipment are the stock type made by the American Gas Furnace Co. of Elizabeth, N. J., and are known as that company's heating machine No. 84. This is one of the company's older type machines, but some of its newer ones are essentially the same in principle and operation, thus being equally well adapted to this work. Inasmuch as this is a stock type furnace, a detailed description is unnecessary, but a general description of the furnace and a detailed discussion of the modifications adapting it to work with oil shale are desirable and will be given.

A drawing of the furnace and complete set-up is shown in Fig. 1. Briefly, the furnace is a steel cylindrical shell, about 3 ft. long with 4-in. fireclay insulation, inside of which is a series of burners and a rotating tube in which the shale, in a wire mesh cartridge, is placed. The heating compartment *B* contains the burners, ten in number, arranged five on a side and at the top of the furnace, as shown in the illustration. It is heated by gas blasted with compressed air (about 4 lb. pressure). The gas and air are led in through the pipes *b* and *b'*.

TEMPERATURE CONTROL

The heating is closely controlled by means of a heat regulator *E*, which is the same as is used on some assay furnaces. It is made by the same company. This regulator is operated by compressed air as power taken from the air line and controlled by means of a base-metal pyrometer *p*, which extends into the firebox proper. This base metal pyrometer, being subjected to the direct heat of the flame in the firebox, makes the apparatus very sensitive and the control, therefore, quite accurate. There was found no difficulty in controlling

FIG. 1. APPARATUS FOR THE DISTILLATION OF SHALES

the temperature on the interior of the furnace, as measured by the pyrometer *D*, to within 10 deg. C.

The tube *A*, which is revolved by the motor *F* geared by a sprocket and bevel gear, as shown in the figure, extends through the furnace. It is 48 in. long, 7½ in. internal diameter, and ½ in. wall. The material of which this particular tube was made is nichrome, but the material usually supplied with the furnace is iron, and for shale distillation processes iron is adequate. Each end of the tube is closed off by heads fastened on by set-screws and thumb-screws, as shown. Stuffing boxes are provided at either end in order that the gases may be carried in and the vapors carried out without the admission of air. In order to confine the shale to the zone between the burners, perforated plates *a* and *a'* were set in. These were held in place by 1½-in. tubes screwed into the end plates. These tubes were perforated so that the gases collecting behind the plates would be carried out by the incoming steam or gas, thus avoiding dead gases. A space behind *a'* is also desirable so that the carbon and finely divided shale being carried out by the gases will settle before it passes into the vapor lines. The tube rotated at about 1 r.p.m.

VAPOR CONDENSATION

A convenient water-cooled condenser was made by using a galvanized iron tank 20 in. deep and about the same diameter. Through this was coiled about 15 ft. of ¾-in. pipe. In shale work it is often desirable to use air condensation before the vapors pass into a water condenser. This may be easily accomplished in this apparatus by erecting a 4-ft. riser where the pressure gage is shown at *M* and equipping it with a drain at the bottom and vapor line to the water condenser from the top. For this riser, 1½-in. pipe is sufficient.

The condensate was caught in glass bottles *e*, *f*, and *f'*, and the permanent gases carried back to measuring or circulating devices through the lead pipe as shown. The container *e*, in which all of the liquid products were caught, is fitted with a drain in order that they may be drawn off and measured from time to time. The containers *f* and *f'* may be filled with dilute sulphuric acid for washing out the ammonia if it is desired to determine this constituent. The boiler was a small low-pressure laboratory type furnishing the desired amount of steam. A circulating fan was installed, as it was desired to study the effects of various gases.

This equipment, supplemented by gas holders and measuring device such as wet test meter, etc., was found elastic enough to meet almost any condition desired in shale distillation work.

Industrial Reconstruction of the French Devastated Region

A note in the November, 1921, issue of *Technique Moderne* shows some figures on the industrial reconstruction of the French devastated region. It is stated that of the 4,805 plants in this region employing 835,298 workmen before the war, only 3,284—i. e., 79.5 per cent—had resumed partial operation as late as Oct. 1, 1921, employing only 397,985 workmen—i. e., only 46.7 per cent of pre-war times. The percentages of workmen now employed in the devastated departments, with the pre-war figures as 100, are: Vosges, 62.2; Meurthe et Moselle, 56.3; Nord, 55.7; Ardennes, 45.3; Marne, 38.0; Aisne, 24.7, and Pas de Calais, 31.9.

Potash in the United States During 1920*

BY M. R. NOURSE

AT THE beginning of 1920 the fear of large imports of foreign potash sales still harassed the domestic potash industry, but as imports did not meet the demand and as prices on imported material early in the year were not materially lower than the prices on domestic salts, a large proportion of the sixty-six plants reporting production remained in operation throughout most of the year.

About 225,000 short tons of potash (K_2O) was imported in 1920. This, with the 48,077 short tons of domestic output, made the available quantity about equal to that normally used in each of the five years immediately preceding the World War. Because of the low prices received for their produce, many of the farmers of the country were unable to take up the promissory notes given by them for fertilizer in the spring of 1920 and were unable to buy the fertilizer they required in the fall. This condition, coupled with the abundance of potash on the market, resulted in a cancellation by the fertilizer-manufacturing companies of orders for domestic potash and greatly reduced the prices of all potash fertilizer materials. As a consequence all the Nebraska plants were closed by the end of December.

The price of potassium chloride (muriate) in the New York market ranged from \$1.75 to \$2.60 a unit during 1920. The net price for the same grade of material from 1911 to 1913 was 76c.

The approximate average prices per unit of potash (K_2O) of the domestic output f.o.b. plant for the same years are estimated as follows:

1915.....	\$3.14	1918.....	\$4.11
1916.....	4.37	1919.....	2.31
1917.....	4.29	1920.....	1.80

The sales for the year amounted to 139,963 tons of crude material, containing 41,444 short tons of potash (K_2O), valued at \$7,463,026, an average price of \$1.80 a unit. The stocks reported on hand at the end of the year were 32,378 short tons of crude material, containing 8,999 short tons of potash.

The plants operating for the primary purpose of producing potash—most of those utilizing brines, alunite, silicate rocks and wood ashes—produced 39,877 tons of potash (K_2O), or about 83 per cent of the total. The output of those producing potash as a byproduct was 8,200 short tons of K_2O .

SALINES

Seventeen plants were in operation in 1920 for the extraction of potash from natural brines. Eleven of these were in the alkali-lake region of western Nebraska (two plants were operated by one company), three were in California and three in Utah. As in several former years, the alkali-lake region of western Nebraska produced more potash than any other locality; the individual plant producing the largest quantity of potash (K_2O) was that of the Utah-Salduro Co. at Salduro, Utah. Some of the plants producing potash from natural brines were operated throughout the year, but by the end of the year all the Nebraska plants and

that of the Salt Lake Potash Co., which utilized brines from Great Salt Lake, were closed.

The pioneer company of the Nebraska district, the Potash Reduction Co.—also one of the pioneers of the American potash industry—made the largest production of potash salts in this district.

It is stated that the cost of producing a unit of potash (K₂O) at the Nebraska plants in 1920, including an item for depreciation, was a little more than \$2. Doubtless the cost was considerably increased because of the dilution of the brines by the heavy rainfall in the spring and summer, which made concentration both difficult and expensive.

Of the three companies in Utah reporting a production of potash sales from brines in 1920 two utilized the waters of Great Salt Lake, and the third utilized the brines of Salduro Salt Marsh, in the extreme western part of the State.

The Salt Lake Potash Co., having a plant on the north shore of Great Salt Lake near Kosmos and producing potash from the waters of the lake by a solar evaporation process, has a yearly capacity of about 40,000 tons. Its product is a low-grade mixture of potassium sulphate and potassium chloride. At the end of the year the plant was closed because of the unsettled condition of the potash market, the high cost of labor and the difficulties of transportation. The Salt Lake Chemical Co., which has for a number of years been producing potassium salts at its plant at Burmester, on the south shore of Great Salt Lake, is a subsidiary of the Diamond Match Co.

The Utah-Salduro Co. at Salduro, 60 miles west of Great Salt Lake, produced more potash salts in 1920 than any other company in the United States. The deposit from which the potash is extracted has been described in former reports of the United States Geological Survey. The composition of the brine is similar to that of the artificial brines of the German potash works. Solar evaporation produces crude salts containing potassium, sodium and magnesium chlorides. These crude salts are boiled with hot brine and on cooling yield high-grade potassium chloride. Both high- and low-grade salts are marketed. Solar evaporation permits great saving of fuel. During 1920 the Utah-Salduro Co. was granted patent to 30,607 acres of land in the Great Salt Lake Desert.

Practically all the potash made from alunite in 1920 was produced by the Mineral Products Corporation,

with plant at Marysville, Utah, now owned by the Armour Fertilizer Works. An accident during the summer of 1920 retarded production somewhat, but new machinery designed to reduce materially the cost of producing potash was partly installed before the plant was shut down early in 1921. The demoralized condition of the fertilizer industry and the consequent lowered price of German sulphate, together with high freight rates, are given as the reasons for closing this plant, which produced a high-grade potassium sulphate and was a pioneer in the domestic potash industry.

The only commercial potash produced from silicate rocks reported to the United States Geological Survey for 1920 was a small quantity made by the Liberty Potash Co. from the wyomingite of Green River, Wyo. The plant of this company was run intermittently from November, 1919, to February, 1920. The product was a low-grade chloride. Since the plant was closed much additional experimental work has been done, and hopes are entertained of refinancing the project and putting it on a sound operating basis.

Only the Government experimental potash-kelp plant at Summerland, Cal., was in operation during 1920 on kelp as a source of potash salts. The capacity of the plant was not increased, but the energies of the force were directed to the development of byproducts, principally bleaching powder and iodine, both of which are now commercialized and placed on the market. The plant capacity for these materials, however, is not yet sufficient to put the experiment on a profitable basis. The output of potash from this plant has increased and the cost of production has steadily decreased. The output in June, 1920, was officially stated as 2 tons a day of 80 per cent muriate.

Status of the Luxembourg Iron Industry

In the review of the Luxembourg iron industry published in the Nov. 10 issue of *Stahl und Eisen* the following figures are conspicuous:

Distillation Studies of Nitric Acid and Sulphuric-Nitric Acid Mixtures—I

Experimental Data on the Equilibria Existing Between Aqueous Nitric Acid Solutions and Their Vapors at Various Temperatures and Pressures—Effect of Dissociation of the Nitric Vapors
—The Phenomena of Maximum Boiling Point

BY PAUL PASCAL

With the experimental assistance of Mr. Garnier

THE preconcentration of synthetic nitric acid from the arc process or the oxidation of ammonia, the final concentration of this acid, even the denitration of waste acids from nitrations, raise a very general question in regard to the equilibria between aqueous nitric acid solutions or mixed acids and their vapors at various temperatures and pressures.

Although in large-scale apparatus of high output this equilibrium is not rigorously attained, an exact knowledge of it has a great practical interest. It has, therefore, appeared worth while to assemble herein the results which we have collected on this question.

As thus far falling in this category one can scarcely but cite the partial work of Saposchnikow [*J. Phys. Chem. russe.*, vol. 37, p. 374 (1905)] on the HNO_3 vapor pressure of mixed acid, and that of Creighton and Smith [*J. Frank. Inst.*, vol. 179, p. 161 (1915) and vol. 180, p. 703]¹ on the distillation of aqueous nitric acid and several nitric-sulphuric acid mixtures under various pressures. And yet this last work appeared just at a time when the results of our research began to find industrial application and a short time before the appearance in *Comptes rendus* [vol. 165, p. 589 (1917)] of a résumé of all our work.

This scarcity of numerical data relative to the commonest operations of the chemical industry has struck all physical chemists who have come in contact with the plant; it provides a free field for numerous and certain very interesting researches, particularly on ternary sulphuric-nitric acid mixtures, which we have specially studied.²

Study of the Binaries: Water, Nitric Acid

It is very difficult to avoid a partial decomposition when a concentrated nitric acid is boiled, and a false boiling point is always found on account of the dilution of the nitric acid vapor by its products of decomposition.

Aston and Ramsay [*J. Chem. Soc.*, vol. 65, pp. 167-73T (1894)] already, in their classical studies on surface tensions, observed that it was impossible to carry an almost colorless acid analyzing 99.8 per cent HNO_3 , above 78.2 deg. C. without boiling, due to the formation in the supernatant atmosphere of a little nitrous product.

Küster & Münch [*Z. anorg. Chem.*, vol. 43, p. 350 (1907)] state that "absolute" HNO_3 , of 100 per cent, colorless in the solid condition, already showed traces of decomposition from the time it melted.

It does not appear that Creighton and Smith were able completely to escape this inconvenience, and moreover in their experiments the pressure was measured at a distance from the boiling liquid, and hence there might be a marked difference (2 to 3 deg., sometimes 6 deg.) between the temperatures of the boiling liquid and the vapor emitted.

Since we could no more hope to prevent the dissociation, at least in the case of anhydrous acid, we preferred to determine its vapor pressure statically.

VAPOR PRESSURE OF PURE NITRIC ACID

The apparatus which was used was quite reminiscent of that employed in our work on the diamagnetism of organic compounds [*Ann. Chim.*, vol. 25, p. 304 (1912)].

The saturated vapor pressure of the liquid was measured by the increase in pressure resulting from its introduction into a space maintained at a uniform temperature and where the volume of the gas phase was maintained constant so that the correction of the expansion of the atmosphere could be avoided.

The increase in pressure was measured, below 30 deg., by a manometer of vaseline oil, freed from its alterable constituents by prolonged shaking with concentrated nitric acid; above 30 deg. by a column of mercury, protected by a layer of the same oil. All these operations were carried out under shelter from direct light.

The determinations offer no reliability above 75 deg.; often even before arriving at this temperature dissociation occurred, initiated by dust or by the too extended maintenance of an elevated temperature; even the vaseline oil was soon attacked. When working with a 100 per cent acid, prepared according to Küster & Münch, we obtained the figures in Table I, which agree well

TABLE I. VAPOR PRESSURE OF 100 PER CENT NITRIC ACID

Temp., Deg. C.	Mm. Hg	Temp., Deg. C.	Mm. Hg
20	23	50	200
26	38	62	350
29	50	74	530
40	112	75	540

enough, with a slight extrapolation, with a normal boiling point lying between 86 and 87 deg., in the absence of all dissociation.

At low temperatures our figures are distinctly lower than those which Creighton and Smith obtained by measuring the boiling point at a given pressure; but at 50 to 60 deg. agreement is re-established and maintained.

HEAT OF EVAPORATION OF NITRIC ACID

It is known that Clapeyron's formula may be written:

$$L = \frac{T}{J} u' \frac{dp}{dT}$$

Translated from *Ann. Chim.*, 1921, New Series, vol. 15, pp. 253 to 290, by F. C. Zeisberg, Chemical Department, E. I. du Pont de Nemours & Co.

¹Note: The first of these is by Creighton and Githens, the second by Creighton and Smith. F. C. Z.

²See Pascal and his collaborators, *Bull. soc. chim.*, 1918-1920, *passim*.

if the specific volume of the liquid as compared with that of the saturated vapor is neglected. If the vapor is regarded as a perfect gas, we may write:

$$pu' = \frac{RT}{M}$$

M being the molecular mass; from which, finally:

$$L = \frac{RT^2}{JM} \times \frac{1}{p} \times \frac{dp}{dT}$$

It is thus found that at 86 deg. $L = 120$ cal. and at 75 deg. $L = 125$ cal., values which almost coincide with the direct determinations of Berthelot. It is noted, moreover, that the heat of vaporization, calculated from the vapor pressure curve, increases distinctly as the temperature decreases, as if at low temperatures the vapor suffered a notable polymerization.

THE BOILING OF AQUEOUS NITRIC ACIDS

Several different but nearly similar apparatus were employed in the course of these experiments, all inspired by the twofold desire to obtain a sample of the vapors and the liquid without interrupting the distillation and to define as perfectly as possible the temperature and the pressure at which the two phases were in equilibrium.

In its most perfect form, achieved in the preliminary experiments, the distillation apparatus comprised a boiling vessel, a vapor cooler and a total condenser for the vapors, all of sealed glass.

A Würtz flask, of 5-liter capacity, half filled with liquid was heated on a sand-bath. It was entirely sur-

second extended only into the vapors. Under normal operation, before withdrawing any samples, they agreed within about 0.5 deg. and the upper part of the air-bath was about 5 deg. above this boiling point.

The cooler was a simple tube cooled on the outside by circulating water at 14 deg. and sealed directly to the condenser. This latter part of the apparatus consisted

FIG. 2. BOILING POINT CONTOUR LINES

essentially of three reservoirs A , B , C ; the first served as a measuring device, the second as a sampler, the third as a guard tube. To C was connected the water-jet pump which exhausted the apparatus, or the reservoir of compressed air used when boiling points above atmospheric pressure were studied.

The measuring tube A had a diameter of 2 cm. and a length of 10 cm. and was graduated; it was surrounded by a cooling bath (if necessary acetone and carbon dioxide snow) to condense all the vapors; B was a Cloez bubbling tube closed by a cock R_6 .

The various cocks shown in the illustration are of different types. R_2 , R_3 and R_6 are simple stop-cocks; R_1 is a stop-cock with an opening through the plug, which enables connection to be made with the atmosphere and B or C , to relieve the vacuum there; R_5 is a three-way cock, of which the openings may take various positions, as 1, 2, 3 or 4. (See Fig. 1.)

The flask being filled by suction through the tube T_1 , R_1 is closed, R_2 is opened, R_6 is closed to the air and R_5 is turned into position 1. Heating is commenced and then as the boiling point, determined by a previous experiment, is approached, the water-jet pump is started to establish the desired pressure.

The ebullition is permitted to become regular to mix the liquid thoroughly and 4 to 5 c.c. at least of liquid is collected in A to rinse the apparatus well. This rinsing liquid is evacuated to the guard tube C by closing R_2 and setting R_5 in position 4, and immediately thereafter the two cocks are replaced in their original positions.

If at this time both thermometers in the Würtz flask indicate the same constant temperature, 2 or 3 c.c. of liquid is collected in the graduated tube, but this time is allowed to pass into the sampler by closing R_2 and putting R_5 in position 3.

After this operation R_5 is replaced in position 4, R_2 is reopened and by means of R_1 the sampler B is connected with the atmosphere, in order that the rinsing acid wetting its walls may be removed through R_6 . A new portion of liquid is then transferred to the sampler, now well rinsed by the condensed acid, by repeating the above operation, and is withdrawn for analysis.

The measuring tube A , in short, serves to measure

FIG. 1. DISTILLATION APPARATUS

rounded by an asbestos jacket provided with glass windows heated interiorly as needed by lamps with carbon filament. Thus all condensation of vapor was avoided before the cooler was reached. (See Fig. 1.)

A standpipe T_1 and a stop-cock R_1 served to empty and fill the apparatus; the tube T_1 connected the flask with a manometer and vacuum regulator; T_1 served to carry away the vapors.

Two thermometers were placed inside the flask; the bulb of the first was immersed in the liquid, that of the

*This appears to be a typographical error in the original article for 74.0.—F. C. Z.

the volume of liquid distilled during these operations and permits a determination of the average composition of the acid which furnished the liquid used for the analysis, owing to the knowledge which we have of the composition of the acid remaining in the distilling flask.

In order to make our results more expressive, we have assembled the results in Table II by grouping under the same head the acids whose composition is about the same. Each partial table thus practically gives the vapor tension curve of the acids of different strengths, and as the pressures have practically the same value in each group, we have at a glance the composition of the liquids and the vapors in equilibrium with them under these pressures at all the temperatures of our experiments. We have given in the "vapor" column the composition of the condensed liquids; they occasionally contained nitrogen peroxide in small quantity, but the resulting proportion of this substance is not necessarily exactly like that which existed in the atmosphere of the apparatus.

It is possible, moreover, to correct for the slight variations in strength and pressure for a single series by tracing the surface of the boiling points θ , which has the concentrations c for abscissas and the pressures p for ordinates. Fig. 2 gives the contour lines of this surface projected on a horizontal plane of reference.

Vertical sections of this surface, parallel to the horizontal axes of co-ordinates, represent either the curves

FIG. 3. BOILING POINT CURVES

of vapor pressures corresponding to a given strength, or the boiling point curves as a function of the strength, for a given pressure.

The system of original curves, projected upon the plan θp , bends back upon itself around the hinge formed by the curves which correspond to 65 to 68 per cent HNO₃ strengths for which the existence of a maximum boiling point is observed. The boiling point curves as a function of the strength are shown by the groups of Fig. 3, on which have been plotted the curves relating to the average pressures used in our experiments—namely, 40, 116, 317, 458, 570, 760 and 870 mm. This graph is completed by the vapor curves (dotted) obtained in the same experiments.

DISSOCIATION OF THE NITRIC VAPORS

In all the preceding experiments it was impossible to prevent a partial dissociation of the vapors as soon as the strength of the acid exceeded 58 per cent HNO₃ and the temperature 50 deg. C. When at the same time both of these limits were exceeded, the atmosphere of

the apparatus became slightly colored and there distilled over a mixture of unaltered nitric vapors, oxides of nitrogen, oxygen and water vapor, in which the partial pressure of nitric acid was necessarily below the value indicated by the manometer. There must then be produced an apparent lowering of the boiling point of the acid supposedly distilling without decomposition, and only the "natural" boiling point is observed, to adopt the expression so frequently used by the Dutch school.

Moreover, a small extrapolation of the preceding boiling point curves to the co-ordinate for anhydrous nitric

FIG. 4. BOILING POINT DEPRESSION

acid yields for this substance apparent boiling points E_a below the real boiling points E_r , which may be deduced from the vapor pressure curves; it is due to this fact, no doubt, that the disagreement originates between our numbers, measured statically, and those of Creighton and Smith, measured dynamically.

At any rate, we observed the figures given in Table III.

TABLE III. BOILING POINT DEPRESSION CAUSED BY DISSOCIATION

P., Mm.	E_r	E_a	Δ
870	91.0	87.0	4.0
760	86.5	82.0	4.5
570	77.5	72.5	5.0
458	70.5	65.5	5.0
317	60.0	56.8	3.2
116	40.4	40.0	0.4
40	26.2	26.2	0.0

The depression of the boiling point, shown by Fig. 4, does not show up at low pressures, for then the liquid distills at low temperatures; it is decreased by high pressures, which partially oppose the dissociation; the maximum deviation occurs around 500 mm. and attains a value of 5 deg. We have indicated a slightly higher depression in a preliminary note in *Compt. rend.*, vol. 165, p. 589 (1917).

MAXIMUM BOILING POINT

We naturally also encountered the well-known phenomenon of a maximum boiling point, corresponding to the time when the acid is emitting a vapor of the same composition as the liquid.

Varying the pressure modifies both the temperature at which this phenomenon occurs and the concentration of the acid which gives rise to it. Thus, we have observed the following results:

Pressure, Mm. Hg	Max. Conc., per Cent HNO_3	Max. Temp., Deg. C.
40	65.0	52.6
116	66.4	72.1
317	66.4	99.0
458	66.4	109.0
760	68.4	121.9
870	68.4	125.5

These values agree with those of Creighton and Smith, who determined, at three different pressures, the final composition of the acid obtained by distilling

various acids of an initial concentration lying between 60 and 80 per cent, thus:

Pressure, Mm. Hg.	Concentration	Temperature, Deg. C.
760	68.18	121.7
360	67.15	99.9
110	66.8	74.2

Diminution of the pressure thus displaces the maximum slightly in the direction of a lower nitric acid content. (See Fig. 2.)

Scientific Faculty of Lille.

(Part II, dealing with the system water:nitric acid:-sulphuric acid and the practical application of these data, will be published in a subsequent issue.)

The Repel-Arc Furnace

THE Repel-Arc furnace¹ essentially consists of a metal framework supporting the furnace bowl and a mast which carries the electrode holder or torch. The frame is substantially made of standard shapes, riveted together. No foundation is required, except in the 1- and 1½-ton sizes. The bowl is made of boiler plate, with seams riveted. It is mounted on trunnions so that it can be tilted for pouring. Small furnaces are tilted by hand; the larger sizes by motor and screw. The bowls

REPEL-ARC FURNACE IN OPERATION IN A FOUNDRY
SPECIALIZING IN SMALL STEEL CASTINGS

are made amply large, to admit of a thick lining, so as to keep heat losses at a minimum. The roof is made of firebrick.

Supported from the mast arm and counter-weighted so that it can be easily raised and lowered is the heating element, sometimes called the torch. This consists of a cylinder with one end closed, made of crucible material. Through the closed end of this cylinder are three round holes in which are placed cast alloy supports for the carbons or electrodes. Each of the three electrodes is

¹S. von Schlegell, U. S. Pat. 1,352,541, Sept. 14, 1920.

carried in a sleeve which rests on the support so as to be pivoted or be free to swing. They are counter-weighted so that the lower ends swing into contact when the current is off. This simple expedient of mounting the carbons so that they are free to swing to and from each other makes the furnace self-regulating.

On account of the fact that the furnace is three-phase and automatically self-regulating, no special transform-

to electrode if it ceases between the electrode and the metal. This constant maintenance of the arc makes the operation of the furnace steady and uniform.

QUICK POURING AND CHARGING

Again, when ready to pour, the heating element is raised in an instant and swung out of the way. The shell can then be tilted forward for pouring. As soon as the pouring is completed, the next charge can be put through the roof opening, the electrodes swung into place and the furnace started again. This saves time and heat, prevents breaking electrodes and makes it possible to repair the lining without disturbing the roof. With the charge prepared in advance, it is an easy matter to pour, recharge and start a 500-lb. furnace in 5 minutes.

To adjust the furnace so that it draws any given amount of power from the line, it is only necessary to move the adjustable counter-weights on the electrode holders. This makes it possible to change the heating rates at will. The vertical movement of the torch as a whole also makes it possible to maintain the arc at the desired distance from the metal, without affecting the electrical operation of the furnace.

Another feature of importance is the fact that the shell or bowl is removable. By having two shells, one can be used for ferrous and one for non-ferrous metals; or one can be relined or the lining patched while the other is in use.

Repel-Arc furnaces are made in the following standard sizes for 22-volt, three-phase operation: $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1 and $1\frac{1}{2}$ ton capacity. On account of the ability to make use of both the direct and indirect system, all furnaces are adapted to the melting of all metals which can be successfully handled in an electric arc furnace, such as steel, iron, copper, brass, nickel, aluminum, Monei metal and the many alloys used in the various industries.

An Improved Scleroscope

AS IS well known, in hardness testing the surface resistance of metals must be overcome as by application of a given force on a spherical point. This operation leaves permanent indentations of a size varying in proportion to the material's resisting power or hardness.

The older way had been to measure the indentation under a microscope or depth gage, then to convert into suitable hardness degrees. This method, however, is not practical on hardened steel, and otherwise it is so uncertain and painstaking as to render it almost unavailable for regular commercial use.

The Shore direct reading principle, embodied in the scleroscope, is more convenient and is applicable to not only soft metals but the hardest steels as well. To this end is utilized a diamond-tipped hammer, which, after falling, indents the metal microscopically and then rebounds to a graduated height which is in exact inverse proportion to the size of the said indentation. Notwithstanding the great speed at which this instrument may thus be operated, full accuracy is maintained. Comparatively little or no nervous fatigue is involved, hence it has best met all requirements of economical and commercial hardness measuring.

In view of this fact, that the scleroscope has met with universal approval and adoption is perhaps needless to mention. The demands made on it recently, however, have been so intensive and often under such adverse

A CROSS-SECTION OF THE REPEL-ARC FURNACE AND ENLARGED SECTION OF AN ELECTRODE HOLDER, ILLUSTRATING THE PRINCIPLE OF OPERATION

ers are required. It can be connected to any 220-volt, three-phase motor supply circuit of proper capacity.

The instant the switch is closed the electrical repulsion and rapid evolution of gases between the carbons force them apart and draw the arc. If the current tends to increase, the carbons are forced further apart, increasing the length of the arc and keeping the current from rising. If the current reduces, the carbons move closer together, shortening the arc and keeping up the current. If the power is shut off and turned on again, the arc is immediately re-established.

BOTH DIRECT AND INDIRECT ARC

A distinct advantage of this new furnace is the fact that it can be operated both as a "direct arc" and an "indirect arc" furnace, which adapts it to the melting of metals of different kinds. The electrode holder can be raised and lowered as a unit. When melting metal of high volatility, the arc can be maintained entirely between the electrodes at the desired distance above the metal. Again, when melting down metal requiring greater heat, the arc can be lowered so as to take place wholly or partly between the electrodes and the metal itself. After the metal is molten, the arc can be maintained entirely between the electrodes and the molten mass if desired. In melting down a charge the arc is not broken by the falling away of the metal as it is melted, because the arc is still maintained from electrode

conditions that its manufacturer, the Shore Instrument & Manufacturing Co., has made a closer study of the advanced conditions of its application, with a view to improving it further. The results were very satisfactory and it is announced that the scleroscope formerly known as Model C has, by virtue of modifications, been listed as Model C-1. The refinements made so increase the flexibility of the operating mechanism that it will give more uniform service even though the adjustments are comparatively approximate and the working conditions, including the skill of the operator, are less favorable.

FEATURES OF THE NEW SCLEROSCOPE

Among the features are: (1) special fine screen *S*, for eliminating dust from the operating mechanism; (2) the leather operating piston formerly used has been replaced by one of tungsten steel, which is practically

IMPROVED SCLEROSCOPE

indestructible; (3) the former rigid adjustments of the hammer-hook mechanism have been replaced by a flexible adjustment *Q* which also greatly prolongs the life of the glass tube; (4) the hammer hooks have been provided with shock shoulders, which eliminate breakage of disalignment of these parts. In addition, more highly perfected glass tubing is being employed.

Altogether, the refinements that have been added to the Improved Scleroscope Model C-1 have greatly increased the ease of operation under all conditions and speeds. This advantage will be appreciated by the painstaking laboratory man, as well as by the modern precision manufacturer, whose problem is one of quantity production.

Synopsis of Recent Chemical & Metallurgical Literature

Combined Iron and Steel.—Dr. Percy Longmuir read a paper on this subject before the Birmingham (England) Metallurgical Society, and is reported by *The Iron and Coal Trade Review*, Oct. 28, 1921, p. 617, to have said that composite articles of iron and steel had been made in Sheffield for 50 years. They are particularly useful for cutters operating at high speed on organic fibers (wood, paper, grass, wool), withstanding vibration and sudden impact better than all-steel tools. A steel cutting surface backed with tough iron may be hardened to equal hardness over its entire face, and needs only regrinding for sharpening, whereas a solid steel blade would break under work if hardened throughout. The former will bend under a shock which would shatter the latter.

Welding soft iron to hard steel is beyond the smith's skill, even though some of them can weld high-carbon metal when making "double shear" steel. It has often been proposed (and done) to pour molten steel about hot wrought-iron bars, or thrust them into the mold after pouring. After rolling, the wrought iron is found to have preserved its identity, but shows the characteristics of "burnt" metal—i.e., "tenderness" and brittleness.

A more successful method consists in using a mold with a vertical partition, filling one half with crucible steel, and almost instantly the partition is removed as the remainder of the mold is filled with molten iron. On cooling, the composite ingot is found to be securely welded; it is dressed, cogged into a bar, and rolled into plates, ready for annealing, forming into tools, and hardening. Excessive piping was very rare in ingots which had been properly welded, and the latter was purely a matter of good workmanship. The raw materials were of best stock and crucible melted, and treated according to tool steel practice. Although high-speed steel and other complex alloys have been used, the ordinary materials are as follows:

	C	Si	Mn	S	P	Brinell
Low-carbon iron...	0.08 to 0.15	0.05	0.30	0.035	0.035	120
Steel	0.75 to 1.40	0.10	0.30	0.03	0.03	

A knife made from the combined iron and steel gave a Brinell hardness on the steel face of from 600 to 627 at distances ranging from 1 to 4 in. from the cutting edge. A solid steel knife of the same shape and for the same purpose had a Brinell hardness of 512 1 in. from the edge, 444 at 2 in., 228 at 3 in. and 207 at 4 in.

Stainless Iron.—We have already published a note¹ to the effect that stainless iron has been marketed in England for automobile bodies. Dr. Leslie Aitchison has now read a paper before the British Institution of Automobile Engineers (November, 1921, meeting) on "Chromium Steels and Irons." He noted that freedom from corrosion is definitely an attribute of chromium; 25 per cent of nickel not being the equal to one-half that amount of Cr in this respect. It is not well appreciated that the properties of the steels are profoundly affected by carbon; too high carbon may accelerate corrosion, but on the other hand carbon as low as 0.07 gives easily forged metal little subject to surface defects. It is thus very useful for sheet, strip or intricate drop forgings, even if weaker than stainless "steel" (C 0.40±). Its price, too, is lower. The effect of carbon can easily be seen by comparing steels containing approximately 0.20 Si, 0.20 Mn, 12.00 Cr, 0.50 Ni:

Carbon Content	Maximum Stress After Quenching and Drawing at—			
	500° C.	600° C.	700° C.	750° C.
0.07	144,800	98,200	80,800	73,400
0.15	179,000	112,800	93,600	87,800
0.37	210,000	128,200	108,000	
1.01			88,800	73,600

A lower chromium steel (C 0.11, Cr 4.72) has strength slightly less than the first one given above, but rusts fairly easily.

¹CHEM. & MET. ENG., Oct. 12, 1921, p. 717.

Current Events

in the Chemical and Metallurgical Industries

Fails to Produce Gasoline From Peat in Court

In the course of the civil action alleging fraud (see CHEM. & MET. ENG., vol. 24, p. 985; June 1, 1921) which William H. Doolittle, of Woodmere, L. I., brought against Louis E. Enricht, president of the Enricht Peat Gasoline Co., Inc., the inventor was given an opportunity to demonstrate his process in the Nassau County Court before Judge Lewis J. Smith.

On Dec. 8 Charles Krainzler, of Farmingdale, testified that he had been secretary of the company until convinced that it was not a legitimate enterprise. He then resigned. (See CHEM. & MET. ENG., vol. 24, p. 506, March 23, 1921.) He also testified that the gasoline which was apparently produced from the peat really came from a secret receptacle in the apparatus which was filled prior to the demonstration. Accordingly, previous to the court demonstration on Dec. 9, the entire apparatus was taken apart and carefully inspected by three chemical experts, Dr. William B. Stoddard, Dr. Irving Hochstadter and F. J. Kenny. Difficulty was experienced in attempting to take apart the suction-pressure pump and a recess was granted to enable Mr. Enricht, accompanied by the experts and both attorneys, to take the pump to a garage and open it.

Before the apparatus was assembled, Dr. Stoddard explained to the jury the function of each part as he understood it from his inspection and from the inventor's diagrams, never having seen the apparatus in operation. The equipment differed somewhat from that described on page 214 of the Feb. 2, 1921, issue of CHEM. & MET. ENG. In the first place, there was no mention of methanol, the only product being gasoline. A bicycle pump served to force air through a copper coil inclosed in a brass case and then through the combustion chamber in which the peat was to be burned. This was connected to a catalyst chamber containing staggered baffle plates supporting the catalyst. A three-compartment trough for water formed the bottom of the chamber. Next came a sort of gas holder formed of a capped brass pipe fitting closely inside a piece of iron pipe. A second catalyzer chamber followed. The gases could be drawn through all this apparatus by the suction side of the double-acting pump referred to above, and forced under pressure through the remaining parts, which consisted of a soldered brass can and a small receiving tank.

About 2 o'clock Mr. Enricht began to assemble the apparatus under the close scrutiny of the experts and the jury. Innumerable small bolts had to be put in place and tightened, so that it was 5 o'clock before the inventor announced that everything was in readiness for the test.

After filling the base of the first catalyzer with water, peat was placed in the combustion chamber and ignited. Vigorous operation of the bicycle pump soon filled the court room with smoke. The heavy suction-pressure pump was then manned by a court attendant. Smoke continued to pour out, the pumps wheezed and the court attendants were relieved as they became fatigued. After several minutes, Mr. Enricht gave up the experiment, explaining, however, that the apparatus was not air tight after having been re-assembled and that consequently he could not maintain the required pressure. In answer to a question by the judge, he admitted that the demonstration was over. His attorney attempted to arrange for a further demonstration after the apparatus had been made air tight, but the judge refused permission.

On the witness stand, Mr. Enricht admitted that his name had been Henricht in Germany and that he had been fined \$500 in the federal court in Chicago in 1902 for using the mails for fraudulent purposes in connection with a land deal. In answer to one question he insisted that he never claimed to make gasoline, but that his product was naphtha or rather hexane, C_6H_{14} . He also admitted that in spite of

the protest of the plaintiff's lawyer, he had worked the suction-pressure pump vigorously while taking it to the garage, that he had removed what appeared to be gelatine from the barrel of the pump after it had been opened in the garage and that naphtha was found in one of the rubber tubes connected to the pump. He stated that this naphtha must have remained in the pump since the last demonstration, although this was made about 2 months ago.

A copy of a citation from the United States Patent Office in regard to an application for patent filed Sept. 25, 1920, was also introduced into the record. All claims were rejected because the process was clearly inoperative and contrary to the now known laws of physics and chemistry. For further consideration the affidavits of several impartial witnesses would be required. It was suggested that the Bureau of Standards or the Bureau of Mines might be willing to test the process, if requested. The need for having two separate catalyst chambers with merely a gas holder between was questioned, as well as the reason for using such a high pressure, since the supposed product, C_6H_{14} , is a liquid under normal conditions.

The trial was still on as this magazine went to press.

German Potash Syndicate Captures American Market

At a meeting of the New York Section of the American Chemical Society Friday evening, Dec. 9, Dr. John E. Teeple, chairman of the section, announced that according to a copy of a contract in his possession, thirty-four American users and distributors of potash for agricultural purposes have entered into an agreement whereby at least 75 per cent of the requirements of the group for the period from June 1, 1921, to April 30, 1922, shall be purchased from the Deutsches Kalisyndikat.

As set forth in the copy of the contract, the total of the minimum purchases on a 75 per cent basis for all thirty-four companies is only 35,680 short tons of K_2O , a figure well within the productive capacity of the American potash plants. Yet it is understood that the American firms were not given a fair opportunity to bid, although they expressed willingness to meet foreign prices.

Dye Investigation Ordered

The United States Senate has authorized its Committee on the Judiciary to investigate "the charge that the dye industry is controlled by a combination of corporations which is in fact a monopoly and has employed agents, attorneys and lobbyists to influence Congress in behalf of special legislation to the interest of such monopoly, and to investigate the activities and methods of importers of dyes from Germany and their agents, attorneys and lobbyists to influence Congress in behalf of special legislation and to investigate the dye and chemical industries of the United States and the supply and distribution methods within the United States and elsewhere of the German dye and chemical industries with a view to recommending proper legislation."

That portion of the resolution which refers to the investigation of the practices of importers was an amendment to the original resolution proffered by Senator Frelinghuysen.

During the consideration of the amendment, Senator Frelinghuysen made an extended speech in which he stated that ample reason did not exist for any such investigation and that the purpose behind it is entirely unfriendly to the great American industry. In his address, Senator Frelinghuysen had suggested that the Department of Commerce, with its commodity specialists, is better equipped to conduct the investigation than is the Committee on the Judiciary.

The sub-committee which will conduct the investigation had not been appointed at the time of this writing.

More Plants Increasing Operations

Rubber. The Excell Rubber Co., Wadsworth, Ohio, has resumed operations, following a shut-down for a number of weeks. The company has been reorganized.

The Ajax Rubber Co., Trenton, N. J., has resumed production at its plant, following a shut-down due to a strike of operatives. A settlement has been reached and about 1,000 men have returned. The mill will operate on a full-time, or three-shift, basis for the manufacture of automobile tires.

The Millville Rubber Co., Millville, Mass., a division of the United States Rubber Co., specializing in footwear products, has increased its working force for a night-shift operating schedule.

The B. F. Goodrich Co., Akron, Ohio, is increasing production in its automobile tire department approximately 1,200 tires a day, making a total output of close to 10,000 tires daily at the present time. About 500 employees have been added to the working force in different departments.

Ceramic. The Homer Laughlin China Co., Newell, W. Va., and East Liverpool, Ohio, is operating at capacity and close to normal.

The Warwick China Co., Wheeling, W. Va., has placed its plant on a full-time production basis.

Crane & Co., Chicago, Ill., have placed their recently acquired plant of the Mutual Enamelware Co., Chattanooga, Tenn., on a production basis. The name has been changed to the Crane Enamelware Co.

The American Bisque & Novelty Pottery Co., Williams-town, W. Va., is operating at capacity, and plans for plant extensions for greater output.

The Robinson Clay Products Co., Akron, Ohio, has developed greater production at its plant, and plans to maintain operations at a comparatively high rate throughout the winter period.

The Edwin M. Knowles China Co., East Liverpool, Ohio, with other plants at Chester and Newell, W. Va., has adopted a normal working schedule at all plants.

The Carr China Co., Grafton, W. Va., has increased production at its plant.

The Chelsea China Co., New Cumberland, W. Va., has advanced operations at its plant to a point close to normal.

Iron and Steel. The United States Cast Iron Pipe & Foundry Co., East Burlington, N. J., has increased production to a point of from 45 to 50 per cent of normal at its different foundries.

The East Penn Foundry Co., Macungie, Pa., manufacturer of brass, iron and other castings, is operating at full capacity, with good advance orders for future production.

The E. & G. Brooks Iron Co., Birdsboro, Pa., has placed its local sintering plant on a double operating shift. The plant was destroyed by fire some time ago and has been completely rebuilt, with installation of new machinery.

The Wickwire-Spencer Steel Co., Buffalo, N. Y., has increased operations at its local finishing mill to a point of about 75 per cent of normal. One blast furnace is in operation. Production is being increased at the New England mills of the company.

The Carnegie Steel Co., Steubenville, Ohio, has placed its local plant on a 60 per cent capacity basis.

The Gulf States Steel Co., Gadsden, Ala., is said to be planning to blow in its local blast furnace early in January.

The Fabricated Steel Co., Leetonia, Ohio, has resumed operations after a curtailment of a considerable period.

Miscellaneous. The American Cellulose & Chemical Mfg. Co., Amcello, near Cumberland, Md., has commenced production at its new local plant for the manufacture of celloid, artificial silk, etc., and daily shipments of material will be made. A gradual increase will be made in the working force as conditions warrant.

Industrial Plants in Georgia Expand

The Georgia Manufacturers' Association, Atlanta, reports that industrial conditions are better in the state than at any time for the past year. A recent canvass shows that 55 per cent of manufacturing plants are operating at full capacity; 35 per cent under a part-time schedule; and about 10 per cent of state plants are idle.

First Report of Federal Power Commission

Judging from the applications which followed the passage of the federal water-power act of 1920, the Federal Power Commission concludes in its first annual report that the production and use of hydro-electric power in the United States will be the outstanding industrial fact of the next 25 years. In 16 months, following the passage of the act, there were filed with the commission 185 applications for preliminary permit and 85 applications for license to develop water power, aggregating 11,060,000 primary and 5,766,000 secondary horsepower. To complete these projects would mean a capital expenditure exceeding in the aggregate two billion dollars. The following table shows the geographical distribution of applications:

DISTRIBUTION OF APPLICATIONS BY STATES

	No. of Applications	Horsepower	
		Primary (90 per Cent of Time)	Estimated Installed Capacity
Alaska.....	31	217,200	279,060
Alabama.....	4	35,025	147,000
Arizona.....	13	3,544,160	4,750,000
Arkansas.....	4	94,100	169,000
California.....	80	2,118,810	4,057,075
Colorado.....	4	50,660	100,900
Connecticut.....	2	20,000	32,000
District of Columbia.....	1	47,300	50,000
Florida.....	4	6,540	12,100
Idaho.....	12	90,650	189,185
Illinois.....	1	41,450	50,000
Kentucky.....	1	96,000	160,000
Louisiana.....	1	40,000	55,000
Minnesota.....	7	38,150	79,300
Mississippi.....	1		
Missouri.....	4	8,000	55,000
Montana.....	14	319,875	532,450
Nevada.....	1	(Transmission Line)	
New Jersey.....	3	361,400	432,300
New Mexico.....	1	2,750	25,000
New York.....	16	1,712,845	2,192,830
North Carolina.....	3	3,160	16,400
Ohio.....	2	210	250
Oklahoma.....	3	34,880	54,000
Oregon.....	10	466,060	832,860
Pennsylvania.....	1	38,400	80,000
South Carolina.....	2	2,000	8,000
South Dakota.....	1	(Transmission Line)	
Utah.....	6	918,015	1,212,465
Virginia.....	2	29,760	110,000
Washington.....	18	699,930	1,112,640
West Virginia.....	2	11,200	20,000
Wisconsin.....	1	10,000	20,000
Wyoming.....	4	1,410	1,410
Total.....	260	11 059,910	16,826,225

Up to Nov. 1 final action has been taken on 59 applications, in which 27 preliminary permits and 31 licenses were authorized, involving 1,415,600 primary and 2,627,000 installed horsepower. Of the projects under license construction is now under way on the following:

	Primary	Installed Hp.
Henry Ford & Son, Inc., Hudson River, N. Y.....	3,640	6,100
Niagara Falls Power Co., Niagara River, N. Y.....	341,500	572,230
Southern California Edison Co., Big Creek, Cal.....	165,000	545,000
Alabama Power Co., Coosa River, Ala.....	21,760	110,000
Snow Mountain Power & Water Co., Eel River, Cal..	9,500	16,670
Western States Gas & Elec. Co., American River, Cal..	6,400	6,400
Wisconsin-Minnesota Light & Power Co., Chippewa River, Wis.....	10,000	20,000
(Preliminary construction only)		
Total.....	557,800	1,276,400

The commission finds itself handicapped in passing on many engineering and economic problems due to a ruling of the Comptroller of the Treasury that the commission is not empowered to employ persons other than its executive secretary. This makes it necessary to rely upon assignments or detail of individuals from other executive departments of the government, which is a very unsatisfactory method of administration. The commission feels that the law should be amended to permit it to employ the proper engineering personnel.

Civil Service Examinations

Vacancies in the Chemical Warfare Service, Edgewood Arsenal, Edgewood, Md., will be filled from the following examinations:

Chemist, \$3,600 to \$5,000 a year; associate chemist, \$2,500 to \$3,600; assistant chemist, \$1,800 to \$2,500. Applications for these positions will be received on Form 2118 until Jan. 10, 1922. Chemical laboratorian, \$1,200 to \$1,500; examination will be held Jan. 11, 1922.

Practical Use of Helium Demonstrated

"The practical use of helium as a gas for the inflation of airships has been demonstrated beyond a doubt." This statement was authorized by the Navy Department after the successful flight of the C-7 from Hampton Roads to Washington and return. The men in charge of the trip declare that the ship maneuvered very much better than when inflated with hydrogen and since the gas does not expand and contract as rapidly as hydrogen, it makes for economical operation. During the entire time that the C-7 was inflated, there was no helium lost by valving. The most striking deduction from the trip, however, is that, heat conductivity of helium being less than hydrogen, it practically eliminates the variation in the lifting power of different portions of the bag. This is of the greatest value

THE FIRST HELIUM-FILLED AIRSHIP

in maneuvering. In addition, helium is twice as heavy as hydrogen, and therefore the bag possesses twice the stability as when inflated with hydrogen. Much greater speed can be attained with a helium-filled ship. An extract from the Navy Department's statement issued in connection with the flight is as follows:

"Helium, next to hydrogen, is the lightest gas known. It has 92 per cent of the lifting power of hydrogen and for military purposes possesses an inestimable advantage over hydrogen in that it is non-flammable. The natural gas wells in the United States afford a practical monopoly of the known sources of supply. According to the latest estimates, helium is escaping into the atmosphere at the rate of 1,250,000 cu.ft. a day, or at a rate sufficient to fill four large airships a week. The refrigeration process is employed to obtain helium. In this process every constituent present in the natural gas is liquefied except helium, which is expelled into suitable containers for storage. The application of this process to the extraction of helium has not been perfected, but the line of development is reasonably clear."

Dr. Joseph S. Ames, chairman of the National Advisory Committee for Aeronautics, is recommending that the government acquire and seal for future use the best helium-producing gas fields; that experiments must be continued in the development of an efficient and economical process for the extraction of helium. He states that with large reserves of helium and the development of types of airships to realize fully the advantages in the use of helium, America would possess resources with which no other nation could compete.

Extra Zone Postage on Chem. & Met. Canceled

The extra zone postage west of the Mississippi River, which has been charged for some time past on **CHEMICAL & METALLURGICAL ENGINEERING** and other McGraw-Hill papers, has been canceled by action of the company. There has been no change in the rates of postage charged by the government, but the owners of **CHEMICAL & METALLURGICAL ENGINEERING** felt that by absorbing this extra cost they could remove a frequent complaint of discrimination against Western subscribers. Extra postage heretofore charged to Canada, Alaska, Hawaii, Philippines, Porto Rico, Canal Zone, Cuba, Mexico, Honduras, Nicaragua, Dominican Republic, Salvador, Peru, Colombia, Bolivia and Shanghai, China, has also been canceled.

Annual Report of the Secretary of Commerce

Herbert Hoover has transmitted to the President the ninth annual report of the Secretary of Commerce, covering the fiscal year 1920-1921. On assuming office March 4, 1921, the Secretary gave attention first to reorganization of departmental expenditures and second to the reorganization of bureaus in his department directly concerned with industry and trade, in order that they might give better service. The reorganization of departmental expenditures has enabled the department to revise its estimates of expenditures for the fiscal year 1921-1922 with a net saving of about four million dollars, or 16½ per cent of the available appropriation.

The Secretary calls attention again to the great need of a government-owned building for the department; of a national archives building of fireproof construction; and of a revision of the increase of per diem allowance for traveling expense from \$5 to \$7.

The Bureau of the Census, in addition to its regular duties, has been assigned the work of compiling statistics for a monthly report known as the Current Survey of Business, to show the trends of business and industry throughout the country. This monthly report has already proved useful to the business public and plans are under way for its improvement. Attention is called to the possibility of assigning to the Bureau of the Census investigations of other government bureaus, such as the Geological Survey, Bureau of Mines, etc. This suggestion is made in the interest of avoiding duplication of work.

The Bureau of Foreign and Domestic Commerce has improved its foreign service through commercial attachés and trade commissioners. Membership changes in personnel have been made in the interest of more efficient work. The report gives in considerable detail the work of the bureaus' representatives in different parts of the world, with typical examples of the practical value of this service. Monthly cable service is published in *Commerce Reports*, comprising strictly up-to-date information from the bureau's representatives throughout the world. *Commerce Reports* has been revised in size and make-up, much to the advantage of both the bureau and the readers. The practice of grouping various articles under commodity headings is an improvement of considerable value.

The work of the Bureau of Standards has been devoted to weights and measures, electrical standards, investigations in heat and pyrometry, optics, engineering physics, metallurgy, ceramics, and miscellaneous materials. The chemical division co-operates with all other divisions of the bureau, as well as with other departments of the government. Thus valuable assistance has been given to the Bureau of Engraving and Printing in connection with the production of engraved plates by electrolytic methods. The chemical division has also served the Air Service of the Army and Navy by testing balloon fabrics. It also rendered service to industry in general by preparing and distributing 4,016 standard samples of metals and alloys.

Federal Trade Commission Amends Complaint Against Steel Corporation

The complaint of the Federal Trade Commission against the United States Steel Corporation and its subsidiaries has been amended to make its charges more specific and to simplify the issue and expedite the hearings. The issue in the amended complaint is the same as that contained in the original complaint.

The original complaint charges the corporation and its subsidiaries with discriminating in price between the purchasers of all of its rolled steel products. The amended complaint makes precisely the same charges with respect to each particular rolled steel product. The amended complaint, as did the original, charges that such discriminations are in violation of the Clayton and federal trade acts for the reason that they are not made because of any difference in the grade, quality or quantity of the product sold, nor because of different cost of selling or transportation, nor because the different prices were made in good faith to meet competition.

Additional Commodity Divisions, Department of Commerce

In view of the propitious start made by the commodity divisions of the Department of Commerce, the President and the director of the budget have approved a request for an appropriation of \$540,000 for the continuance of the work in the interest of the export industries during the next fiscal year. This is an increase of \$290,000 over the amount appropriated for this work during the current fiscal year. It is proposed to set up seventeen additional commodity divisions, as follows: vegetable oils and breadstuffs; meat and dairy products; canned goods; cotton and cotton goods; wool and woolen goods; petroleum; dyes and drugs; heavy chemicals; paints, varnishes and tanning materials; hardware and tools; glass and earthenware; paper; non-ferrous metals; transportation and communication; foreign investments; advertising, packing and credit methods; maps and commercial geography. The existing commodity divisions are: iron and steel; lumber; shoes; rubber goods; heavy machinery; implements and vehicles; automobiles; electrical goods; foodstuffs; textiles; fuels; leather; office appliances; specialties. The iron and steel division is receiving an allotment of \$17,000; the lumber division \$14,000, the shoe division \$12,500 and rubber goods division \$14,000. The other existing divisions are each allotted \$15,000 for their annual expenses. It is planned that each of the new divisions is to be allotted \$15,000. In each case the chief of the division is to receive a salary of \$6,000 and the assistant chief \$2,000.

For the general work of promoting commerce, Congress is asked to appropriate \$524,050, an increase of \$199,050 over the appropriation for the current year. Under this appropriation it is proposed to establish new trade commissioner offices in Russia, in Greece and in Canada. It is also the plan to undertake special technical investigations in connection with iron and steel in England, Belgium, Germany and France; in connection with lumber, in the Scandinavian countries; in connection with electrical goods, in Germany, France and Belgium; in connection with fuels, in England, Belgium and Germany; in connection with leather, in Germany, Spain, Holland and Belgium. Similar investigations are to be undertaken covering office appliances and specialties.

In addition, \$213,650 is asked to promote further the commerce between the United States and Latin America. This is an increase of \$113,650 over the current year's appropriations. A portion of the increase is to be applied to the establishment of new trade commissioner offices in Cuba, Colombia, Uruguay and Venezuela. New technical investigations are to cover chemicals, hardware, tools, implements, glass and glassware and foodstuffs.

For promoting commerce in the Far East, \$235,650 is asked. This is an increase of \$85,650. It is proposed to establish under that appropriation new trade commissioner offices in Delhi, Bombay or Calcutta and in Canton. New technical investigations to be undertaken in the Far East would cover textiles, vegetable oils, silks, fibers and petroleum.

Chilean Nitrate Situation

Large nitrate sales in London have greatly encouraged the Chilean producers, according to advices reaching the Department of Commerce. The agreement reached between the Nitrate Producers' Association and the Nitrate Pool, of London, caused a decided rise in the exchange value of the Chilean peso. A part of this gain was lost because of the report that the agreement provided for a material reduction of existing stocks in Europe before further exports were to be attempted. The recent brisk demand for nitrate, however, promises to consume the European stocks in a shorter time than had been expected.

The consul at Iquique reports September nitrate production to have been 1,493,229 quintals. In September of 1920 the production was 4,501,850 quintals. The present rate of production is practically double the rate of exportation, with the result that stocks in Chile are increasing rapidly. The consul states that 29,000,000 quintals has been estimated as the probable 1921 production. The 1920 production of nitrate was 55,514,000 quintals.

Dental Amalgams

No organization not primarily devoted to dental interests ever met in the Dental Dispensary at Rochester until Monday evening, Dec. 5, when the local branch of the American Chemical Society assembled there to hear an address on "Dental Amalgams" by Dr. Arthur W. Gray of Milford, Del.

Dr. Harvey J. Burkhardt, director of the dispensary, gave a short talk concerning the work he and his associates are doing in preventive dentistry, starting first with the children in the schools.

Dr. Gray, in his address, said that dental amalgams are made by the dentist when he mixes dental alloy and mercury before putting the mixture in the cavity to be filled. Some of the best amalgams when hardened have the strength of steel. The older amalgams were not nearly so good and frequently broke.

A dental alloy is made of silver and tin containing from 40 to 70 per cent of silver. Small amounts of other metals such as copper, zinc and gold or platinum are sometimes used. The metals are weighed, then melted and cast into ingots. Any iron that may be present is then removed and the alloy is annealed.

The dentist mixes the alloy with mercury, any excess of which should be expressed. As amalgam is packed into the cavity still more of the mercury is pressed out. The polishing should not be done the same day because of changes taking place in the amalgam. After the alloy is in the tooth it hardens rapidly at first and then more slowly for a week or 10 days. Sometimes it will contract so much as to leave a crevice around the filling, or it may expand so as to crack the teeth.

Alloys of a lower silver content are easy to amalgamate, but they will crush. The alloys of high silver content are much harder to work; they retain much more mercury and are far more lasting. Low-silver alloys were used up to 1895 and unfortunately some are still used because they are easier to handle and cheaper.

The first well-organized and comprehensive work on dental alloys was done by Dr. G. V. Black, a dentist with a medical education, and an old-time scientist. This work was carried on from 1895 to 1897. If an alloy is cut up into shavings it will continue to change for months and even years. It becomes easier to work and expands less. Dr. Black thought this aging was due to oxidation, but later decided it was due to temperature, the higher the temperature the faster the aging. He organized a class of manufacturers and taught them how to make alloys and how to anneal them so there would be no changes. In 1905 Dr. Ward through many experiments showed the necessity for controlling the temperature while annealing.

Dr. Gray is convinced that the contraction of the amalgam is due to the formation of a silver mercury compound when the silver-tin alloy is mixed with mercury. Later this crystallizes and there is an expansion. By extensive experiments Dr. Gray has found out the effects upon contraction and expansion by using different temperatures, different pressures and length of time for trituration. These were made very clear by graphs used with the lantern slides. Following the lecture Dr. Gray showed samples of alloys.

Illinois Short Course in Ceramic Engineering

The regular biennial two weeks short course in ceramic engineering will be given next January at the University of Illinois, between Jan. 23 and Feb. 4. The subjects covered will include elementary physics and chemistry; the origin, classification, winning and refining, and testing of clays; the shaping, drying and burning of clay products; bodies and glazes; the technology of glass; refractories and refractory products; kiln construction; coal and gas fuels; engines and boilers, dynamos and motors, equipment control; pyrometry; drafting and reading of drawings; and business law.

The complete program will be ready for distribution early in January and copies may be obtained by addressing the Department of Ceramic Engineering, University of Illinois, Urbana, Ill. The course is open to all who are interested and can be taken to advantage by any one having a common school education. There are no tuition fees.

Institute of Baking Is Opened in Chicago

The American Institute of Baking, behind which is the American Bakers' Association, has recently transferred its activities from Minneapolis and become established at 1135 Fullerton Ave., Chicago. The institute has absorbed the Wahl-Henius Institute, together with the property at the above location. The history of the Wahl-Henius Institute begins 35 years ago with the establishment of a crude analytical laboratory operated by Dr. Max Henius and Robert Wahl, two analytical and consulting chemists. The institute operated for many years in the study of scientific brewing; and with the new change will come the working over of the plant to serve the bread-baking industry.

Mechanically speaking, there is little difference in the processes of analyzing and experimenting in bread and beer, so with comparatively few changes the building has become a workshop of the baking industry, with an experimental brewery turned into a practical bakery plant.

The institute has four large laboratories and a special laboratory for students; class rooms, lecture rooms, scientific library, auditorium and many other facilities. Dr. H. B. Bernard has moved from Minneapolis to Chicago to become head of the combined organization. Under his direction the institute is to put the baking industry under higher technical control by producing scientific bakers.

Report of the Chemist, Department of Agriculture

In his report of July 1, 1921, as chief of the Bureau of Chemistry, Department of Agriculture, Dr. C. L. Alsberg reviews the work of the various laboratories under his direction. The work of the bureau is of two kinds: Scientific research and enforcement of the food and drugs act. In the realm of scientific research the bureau has established a number of laboratories devoted to special purposes. The report concerns itself in detail with the work of these various laboratories and must be consulted for a comprehensive idea of their investigations. The names of the various laboratories, suggestive of their scope, are as follows: Water and beverage; microchemical; microbiological; cattle food and grain investigation; pharmacognosy; drug division; pharmacological; carbohydrate; oil, fat and wax; citrus byproducts; food research; dehydration; protein investigation; phytochemical; leather and paper; insecticide and fungicide; and color investigation.

One of the most important parts of the bureau's work has been conducted in office of development, which was established in 1920. It has engaged in various activities looking toward the commercial development of discoveries of the bureau's staff, with a view to creating an industrial outlet for agricultural products. The office of development work has also made some excellent investigations of grain-dust explosions and fires.

Proper Functions of Trade Associations to Be Defined

What functions and activities trade associations may legally engage in will soon be announced by the government. E. W. McCullough, manager of the fabricated production department of the Chamber of Commerce of the United States, told the American Face Brick Association in annual convention Dec. 2 at White Sulphur Springs, W. Va. He said that such a statement would have been issued before this but for the fact that several government cases are now pending against certain trade associations, involving such questions as the proper use of statistics, open price plans and averages in cost accounting.

According to Mr. McCullough, Secretary Hoover desires closer contact with the industries through their associations, but Secretary Hoover has intimated that such organizations should put themselves in position to speak for their industries by including in their membership the largest possible representation, and also through the perfection of their machinery for gathering, analyzing and compiling all desirable information of service not only to themselves but to the government and the public as well.

It is to make for such co-operation that the government is expected to define the proper functions of a trade association, Mr. McCullough said.

Chemical Items in U. S. Budget

While the outstanding chemical appropriation in the federal budget is that of \$1,500,000 for the Chemical Warfare Service, there are chemical activities in practically every executive department and in some of the independent agencies. In many cases the money for chemical activities is not segregated. Those which are segregated are as follows:

Bureau of Chemistry. For investigating chemical problems relating to the composition, action and application of insecticides and fungicides, \$20,000; for collaborating with other departments desiring chemical investigations, \$14,000; for investigations relating to the application of chemistry to agriculture, \$75,400; for the investigation of table sirup and sugar, \$10,000; for the investigation of naval stores, \$10,000; for the investigation of methods for the prevention of grain dust explosions, \$25,000.

Bureau of Standards. To develop color standards with special reference to their industrial use in connection with dyestuffs, inks and pigments, \$10,000; to study methods of measurement and technical processes in the manufacture of clay products, \$25,000; for the investigation of the problems involved in the production of optical glass, \$25,000; for metallurgical research, \$40,000; high-temperature investigation, \$10,000; for the distribution of standard materials to be used in checking chemical analyses and in the testing of physical measuring apparatus, \$10,000; for an investigation of radioactive substances, \$10,000.

Bureau of Mines. For investigations concerning the utilization of heavy clay products, cement, feldspar and other non-metallics, \$35,000; for work at mining experiment stations (a part of which is of a chemical nature), \$175,000.

Geological Survey. For chemical and physical researches including researches with a view of determining geological conditions favorable to the presence of potash, \$40,000.

In connection with the budget, the navy announces its salary scale for technical service. It is as follows: Chief chemist, \$11.36 per day; chemist, \$10.56, \$10.24, \$9.84, \$9.44, \$9.04, \$8.72, \$8.32, \$7.92, \$7.60, \$7.20 per day; assistant chemist, \$6.88, \$6.40, \$6.08, \$5.68, \$5.36, \$4.88 per day; chief metallurgist, \$3,000 per annum; assistant chief metallurgist, \$8.32 per day; chemical engineer, \$9.44 per day; laboratorians (chemical), \$5.36, \$4.56; superintendent, acid plant, \$9.04 per day.

Secretary Weeks Favors Gas Development

In view of what is being said to be taking place in the executive sessions of the Conference on Limitation of Armament, particular significance is attached to the position taken by the Secretary of War in the report which he submitted to Congress on Dec. 8. In that report he made the following reference to chemical warfare:

In reviewing our chemical production, it is apparent that the World War brought a new industry into the field of war production and therefore into close relation with the problem of preparedness for national defense. The preponderantly commercial character of this industry, the necessary progress of which as an element in our industrial system carries with a corresponding efficiency in its application to war purposes, conveys the practical assurance that we shall not prove deficient in the production of war chemicals. At the same time, the close relationship between the production of chemicals for war and the preparation of chemical products for peaceful industry compels a realization of the great benefits to our commercial chemical progress resulting from the activities of the War Department in respect to chemical warfare. Since our Chemical Warfare Service is well organized to keep abreast of our developments, there is every hope that we shall be adequately equipped in respect to chemical preparation for war. Though we may be opposed in principle to the use of poison gas, I am of the opinion that we cannot safely presume a similar attitude on the part of possible opponents and neglect the development of chemical weapons if we wish to insure a successful defense in a possible war. Therefore, since the development is of direct industrial benefit, and will not be wasted in any eventuality, I hope for the continued support of this activity by Congress and by the chemical industries themselves.

Arms Conference Action on Gas

No official confirmation or denial is forthcoming of the report that the American advisory committee has recommended that the use of gas in warfare be outlawed. It is known that very different opinions are held by a number of individual members of the advisory committee, although it is admitted that other influential members of that committee are actively seeking to write into any international agreement that may be reached a paragraph pledging the signatory powers to make no use of gas in warfare.

While Japan was expected to be most active in the effort to outlaw chemical warfare, no such activity has developed. Italy has been apparently the prime mover. The argument advanced by some of the Italians is that their country does not possess the raw materials for chemical munitions, and therefore would be put at a disadvantage if unrestricted use of gas were to be permitted.

Personal

DR. F. W. BOYER has been elected president of the Excell Rubber Co., Wadsworth, Ohio, succeeding Ross Trump.

WILLIAM A. DURGIN has been given a leave of absence from the Commonwealth Edison Co., Chicago, to direct the new activities of the Department of Commerce toward the elimination of waste in industry by simplifying and standardizing commercial practices. Mr. Durgin's new organization will form a subdivision of the Bureau of Standards.

RICHARD A. FEISS of Cleveland, Ohio, was elected president of the Taylor Society at its recent meeting in New York. Other officers were elected as follows: Vice-presidents, Horace K. Hathaway, Philadelphia, and Robert B. Wolf, New York; treasurer, Edward W. Clark, 3d, Philadelphia; managing director, Harlow S. Person, New York; directors, Ray M. Hudson, Peoria, Ill.; J. C. Heckmann, New York; Ida M. Tarbeli, New York; Levi H. Ballou, Walpole, Mass.

H. J. ROLLS, Buffalo, N. Y., has been elected vice-president of the Buffalo Paint, Oil and Varnish Club, succeeding William P. Mott.

DR. EDGAR F. SMITH, president of the American Chemical Society, addressed the South Jersey Section at Carneys Point, N. J., Nov. 22. His subject was "The Early History of Chemistry in America." Officers of the local section elected for the ensuing year included Dr. C. E. Burke, chairman, and Dr. H. D. Gibbs, counselor.

HENRY A. TOBELMANN, metallurgist for the New Cornelia Copper Co., Ajo, Ariz., has resigned to accept a position in New York City. Mr. Tobelmann has been continuously in the service of the Calumet & Arizona Mining Co. since 1906, first at Bisbee, later at Douglas and finally at Ajo, where he had much to do with the development and operation of the hydrometallurgical process there used.

Obituary

BENJAMIN F. GREENE, manager for the Westmoreland Chemical Color Co., Philadelphia, Pa., at New York, died recently at the Long Island College Hospital at the age of forty-nine years.

ROBERT B. HAWLEY, president of the Cuban-American Sugar Co., New York, died at his home, 36 Gramercy Park, Nov. 27, aged seventy-two years. He founded the company of which he was head in 1900, and since that time had been a prominent figure in the industry.

GUSTAV LEVOR, a pioneer leather manufacturer, president of G. Levor & Co., with tannery at Gloversville, N. Y., died at New York City, Nov. 23, aged seventy-one years. The company of which he was head was established in 1875, developing into one of the largest industries in this section.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Dec. 12, 1921.

The chemical market during the past week could be described as fair in some quarters, while in others a falling off was noticeable. The general opinion of leading factors, however, is that an irregular market may be expected temporarily due to outside influences incidental to this period of the year. There is no doubt that a decided change for the better will take place early in the spring of 1922 and there is no lack of confidence regarding business conditions over next year. Large producers reported a good volume of business with their regular consuming trade for shipment over 1922. The probability of further reductions of freight rates might have had a tendency to unsettle prices and in some cases practically to cause the discontinuance of actual production. On the other hand, there is a great deal of consolation shown by the marked improvement in the steel trade. The increased activity in the oil industry has meant the speeding up of new construction and steel mills have been operating at increased capacity. Soap factories are running in normal shape, but textile mills have slowed down to a considerable extent. Glass manufacturers are reporting conditions very favorable, with furnaces working at the highest point of the year. Spot prices have shown a little more flexibility than they did during the past two weeks. Imported sulphide of soda is lower. Prussiate of soda is easier. Imported caustic potash is a trifle lower under a continuance of a quiet inquiry. Bleaching powder is holding quite firm and this also holds true of domestic soda ash. Export sales of solid caustic soda were recorded during the week to Japan and South American countries, but the volume was smaller than noted a week ago. There was a rumor that foreign producers of caustic soda fell down on deliveries to Italy, which allowed the placing of orders involving several thousand tons in the American market. Oxalic acid is holding well under recent quotations. It is understood among large dealers that an order embracing several thousand kegs of chlorate of potash has been placed in Mexico. Prices for this material have been very irregular on spot owing to the free supplies and the limited consuming channels. Although there was no change in spot prices on this commodity, there was a pronounced tendency to keep prices firm. Shipment prices for high test granular salammmoniac were reduced and goods were offered in the late trading at lower prices c.i.f. New York.

CHEMICALS

Spot *bichromate of soda* is attracting only moderate attention and scattered sales are reported a 7½@8c. per lb. In most instances the lower figure was easily available on firm business. The tone of the market was steady, with offerings of a more or less general nature. Manufacturers of *bicarbonate of soda* continue to name 2c. per lb. for barrels f.o.b. works. Kegs are held at ¼c. per lb. higher. Spot offerings are heard around the trade at \$2.30@\$3.35 per 100 lb. A fair inquiry was noted from regular consuming channels, but there was very little additional business recorded. Trade conditions in *caustic potash* have remained quiet and the tone of the market appeared somewhat easier. Sales of imported material were recorded at 5½c. per lb. for the 88-92 per cent grade. The general quotation ranges from 5½@5¾c. per lb., according to quantity. Shipment material is obtainable at \$5.30@\$5.40 per 100 lb. c.i.f. New York. Dealers of *nitrite of soda* quote the market at 6¾c. per lb. and state that small sales are about the only feature of the market. It is quite possible that on a round lot a slight concession might be granted. Imported *prussiate of soda* is quoted a trifle lower on spot and the demand was not as brisk as noted a week ago. Small lots of this material are around the market at 14¼@14¾c. per lb. Shipment prices are holding firm at 14¼c. per lb. It is very doubt-

ful if better than this figure could be done on any future arrivals. *Muriate of potash* is also quoted a trifle easier at \$35 per ton, basis 80 per cent. It is understood that some business has been placed a shade under this figure when round lots were concerned. The market has not shown any real signs of activity on this commodity for the past month and keen competition has driven prices down to a new low level. Leading producers of *copper sulphate* have advanced their prices. The carload price for standard 99 per cent, large crystals, is \$5.65 per 100 lb. Smaller quantities are held at 5½c. per lb. and upward, depending upon the size of order. The advance is believed due primarily to the upward tendency of the copper metal. The domestic demand was rather slow during the month of November. The foreign demand, however, has noticeably increased and American sulphate producers have been able to withstand the competition of foreign interests in Italy and other important centers. Prices for imported white granular *salammoniac* were reduced during the week and the market was established at 5¼c. per lb. for shipment, c.i.f. New York. This is the lowest figure recorded since the war. Domestic producers quote 7c. per lb., f.o.b. works. Prices for light *soda ash* in single bags on spot are being well maintained at \$2.10 per 100 lb. for domestic goods. Some small lot sales have gone through at \$2.15. Brokers around the city are quoting the imported material at \$1.75 per 100 lb. ex-dock New York. Ash in barrels is held at \$2.30@2.40. Leading producers report a fair inquiry for forward shipments and state that sales over next year have been made at \$1.40@1.45 per 100 lb., in single bags and \$1.60 in barrels, basis 48 per cent, f.o.b. works. Sales of spot *arsenic* have been recorded at 6c per lb. The demand is irregular, although business in general has shown some improvement. Shipment material is somewhat firmer with sellers naming 5½c. per lb. Second hands offer solid *caustic soda* at \$3.90@4 per 100 lb. An additional call was noted from South America and the Orient and new business has been placed with these countries. Producers seem to be experiencing a good demand from their consuming trades and state that satisfactory business has been placed for delivery over 1922. Large contracts have been closed at \$2.75 per 100 lb., basis 60 per cent, f.o.b. works.

The general quotation for moderate quantities on contract is \$2.90 per 100 lb. basis 60 per cent, works. Buyers of *cream of tartar* are taking the imported material in moderate quantities at prices ranging from 25@26c. per lb. The market has shown a fair degree of activity since prices have been lowered and quotations held firm in the late trading. Prominent sellers of *oxalic acid* quote the market at 15c. per lb., spot New York. Odd lots were sold down to 14½c. per lb. The demand continues quite active.

COAL-TAR PRODUCTS

The coal-tar products market during the past week has undergone very little change. First hands seem to be getting prices on many products under their own control. This fact has not brought about any stability or uniformity in market prices. Sales during the early part of the week were confined mostly to small lots, but the aggregate amount was quite satisfactory. Inventories are keeping many mills from buying regular requirements and buyers are not disposed to place any forward business until this annual function is out of the way. *Phenol* is in very good demand and *paranitraniline* seemed a little firmer at the close of the week. *H acid* is also a trifle steadier since low-priced goods have become scarcer. First hands in *benzene* are in complete control of the market with no resale goods procurable. Quotations range from 27@33c. per gal. for future delivery. Coke-oven operations have increased to a limited extent and are now about 40 per cent normal. The increased output has not been felt to any extent in the benzene market. Foreign inquiries for *phenol* are being recorded in good volume, but there have not been many sales, as prices demanded by the buyers are quite frequently well below the general market. The tone of the market remains very firm, with prime stocks held up to 15c. per lb. Government surplus stocks are quoted at 12c. per lb., while resale material around the city ranges from 10@10½c. per lb.

The St. Louis Market

ST. LOUIS, Dec. 9, 1921.

Business for the month of November showed an appreciable increase over previous months and it is not expected that the approach of the stocktaking period will cause a cessation in buying for this month, which is based on the fact that the majority of the manufacturers and dealers have consistently kept their stocks at a minimum. Just at the present time buyers are chiefly concerned in covering their requirements for next year by contract, but these are not being freely offered by the producers. Importations continue to be heavy, but the general trend of prices is firm.

ALKALIS

The *alkali* market is somewhat dull. Only small quantities are moving at the prevailing price of \$4 per 100 lb. for the solid in drums f.o.b. point of production. The flake is somewhat more active at 25c. advance over the solid, 76 per cent material. *Soda ash* is in nominal demand, with the same price of \$3 per 100 lb. in barrels prevailing. There has been no change in *bicarbonate* or *sal soda*, the price remaining at \$2.90 and \$2.15 respectively and the market is very dull.

CHEMICALS, DRUGS AND PHARMACEUTICALS

Ammonia water, 26 deg., is in steady demand. The demand and inquiries for *sulphate ammonia*, pure granular, continues to be very good at this time. *Bismuth salts* are moving fairly well in spite of the fact that this is the off season and the keen competition. The *bromide* market is firm with a good volume of business being transacted. *Carbon bisulphide* has fallen off, as the demand from the grain storing trade has been satisfied. In our last letter we called attention to *creosotes* and *guaiacols* being seasonable articles, and factors now report that these commodities are moving very lively, indicating that there is a good demand from the consuming channels, and wholesalers should carry liberal stocks. *Glycerine* is in strong demand, with prices advancing to 15c. in drums. Users are now contracting for their requirements over next year, causing the advance. Business on *hydrogen peroxide* at the present moment is scattered. *Iodides* are moving very nicely with a firm market. Increase in demand for *lithium salts* is reported. The demand for *narcotics* is exceptionally good. The demand at the present for photographic materials is not important in volume. Last week producers advanced their prices on *acid salicylic* and *soda salicylate* and yesterday *acid acetyl salicylic* followed suit. Further uplifts would not prove surprising. *Sulphur commercial* is moving slowly at \$2 per 100 lb. in 25-bag lots, with a slight advance for smaller quantities. There is practically no business in the special brands. *Zinc oxide* is in good demand and makers are very optimistic of the future, expecting an increased demand; the price remains at 7½c. in barrels and 7¼c. in bags f.o.b. works for standard brands. There has been no dropping off of orders for *zinc stearate*. In fact, during the last period, an increase has been manifest.

ACIDS

The heavy commercial mineral acids are assuming a better position and moving in larger volumes. *Carbolic acid*, medicinal grade, continues to move through regular channels. *Acid acetic* is rather slow. *Gallic acid* and *tannic acid* are moving pretty well.

VEGETABLE OILS AND NAVAL STORES

Castor oil is very firm, with the price of 12½c. in barrels and 12c. in returnable drums still prevailing. *Linseed oil* is moving very low due to the dull season in the paint industry. *Turpentine* has advanced slightly, now selling at 84½ in single barrels with a 4c. differential on 5-bbl. lots.

PAINT MATERIALS

The dull season in the paint industries has had a very decided effect on the *barytes* market. The movement is practically nil, although the old price of \$23.50 still holds. Manufacturers expect very little business until after Jan. 1. There has been no change in the *lithopone* market. *Whiting* is moving slowly at \$15 per ton.

The Iron and Steel Market

PITTSBURGH, Dec. 9, 1921.

Steel ingot production in November was at the rate of about 23,750,000 gross tons a year, representing about 45 per cent of the total capacity, against rates of 44 per cent in October, 32 per cent in September, 30 per cent in August and 21 per cent in July. The October rate had been the highest since February.

While the comparison by months shows a continuous increase since July, the November output was not altogether as large as would be expected from the increases in operations that occurred late in October and early in November, and it is evident that a high point was reached not later than the middle of November, since when there has been declining production. A fair estimate is that the rate at present is scarcely over 40 per cent.

The decrease in steel production is a tardy reflection of the dullness that stole over the market at the middle of October, and as the market has not become more active lately, except in tubular goods, further decreases in the rate of operation are to be expected. It appears that some mills are making a special effort to run just now, to give employees some money for the holiday season, and it is not improbable that a number of mills will be closed in the last week or two of the month or the fore part of January.

CHARACTER OF DEMAND

In sheets there is a decreasing demand, chiefly or wholly on account of the season of the year. If allowance be made for the sheet tonnage that goes into large construction work and the manufacture of machinery, and allowance also be made for its being between seasons for the automobile trade, the sheet demand may be regarded as not far from normal. Tin-plate demand is normal for the season, and prospects are that 1922 will be a full normal year in tin-plate consumption. Wire products suffer chiefly from two influences, the season of the year and the fact that buying power of farmers is greatly restricted while the farmer is less disposed than usual to spend what money he has.

STEEL PRICES

Except for the cutting in line pipe and some descriptions of oil-country goods, noted above, steel prices are substantially unchanged. It is obvious that there is a sagging rather than any advancing tendency, but demand is so light, running almost wholly to very small orders, that there is little encouragement to sellers to shade prices. The real final "shake-out" in prices is still to come. It will come when buyers enter the market more freely and offer attractive orders for either prompt or extended delivery. The declines, however, will be quite small compared with what was occurring up to last August.

Bars, shapes and plates generally are quotable at not outside a range of 1.50@1.60c., showing no important change for several weeks. Sheets are quotable at 2.25c. for blue annealed, 3c. for black and 4c. for galvanized. They are well held at these prices, but the market is undergoing no serious test. The \$4.75 tin-plate price is also holding well.

In wire products the swing back to prices ruling before the Sept. 12 advance is now almost complete, although the advanced prices are apparently obtained on small orders in many cases. Contracts entered in anticipation of the Sept. 12 advance were for 60 days, but have been extended where necessary.

PIG IRON

The increased activity in pig iron reported from some districts is not observed in the Pittsburgh valley market, where the only transaction of any consequence reported is a sale of 3,500 tons by a steel interest, out of surplus, to the Trumbull Steel Co., which in this connection abandons its plan of starting its blast furnace Jan. 1, so that the incident is not of a particularly bullish character. The market remains quotable at \$20 for bessemer, \$19 for basic and \$20.50 for foundry, f.o.b. valley furnaces.

Connellsville coke is weaker still, furnace coke not being quotable at over \$3, with possibilities of the price being shaded, while foundry coke of ordinary grade is not strong at \$4. On contracts higher prices are of course asked, but there is scarcely any interest on the part of consumers.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

BATESVILLE—The American Manganese Co. has awarded a contract to the E. C. McCombs Co. for the completion of the concentrating plant at its Polk Southard Mines, to be equipped for a daily output of about 25 tons. The plant is estimated to cost about \$150,000.

California

CHICO—The Standard Oil Co. has awarded a contract to J. J. Brooks, Sacramento, Cal., for the rebuilding of its local oil-distributing plant on Nord Ave., estimated to cost about \$25,000. Work will be begun at once.

LONG BEACH—The Red Seal Refining Co. has acquired property on West Anaheim St. as a site for the erection of a new oil refinery, estimated to cost close to \$1,000,000, with machinery. Plans will be drawn at an early date. H. L. Hagerman is treasurer.

Connecticut

NEW HAVEN—Fire, Dec. 1, destroyed a portion of the plant of the Seamless Rubber Co., Hallock Ave., with loss estimated at close to \$100,000. The company is a subsidiary of the United Drug Co., Boston, Mass.

WINDSOR LOCKS—Following the acquisition of the Windsor Lock Paper Mills by the J. N. L. Smythe Co., 32-34 South Sixth St. Philadelphia, Pa., the former company has been dissolved and a new corporation formed under state laws and name of the Windsor Lock Paper Mills Co., Inc., capitalized at \$200,000. The new company will increase the capacity of the plant. The incorporators are A. T. Johnson, A. W. Hyde and J. H. Williams, 261 White St., Hartford, Conn.

Illinois

CHICAGO—The Crane Co., 836 South Michigan Ave., manufacturer of sanitary fixtures, steam specialties, etc., is having plans prepared for the erection of a 2-story foundry at 4100 South Kedzie Ave., to be 160 x 500 ft. and estimated to cost in excess of \$700,000 with equipment. Graham, Anderson, Probst & White, 8 East Jackson Blvd., are architects. W. J. Clark, company address, is construction engineer.

CHICAGO—The Abbott Laboratories, 4753 Ravenswood Ave., manufacturers of chemicals, have construction under way on a new plant at Fourteenth and State Sts., North Chicago, estimated to cost about \$400,000. It will consist of a number of buildings, with main structure 4-story and basement. It is proposed to expand the present plant in the spring and ground for additional structures will be broken at that time. E. H. Ravenscroft is vice-president in charge of construction.

CHICAGO—The Nemo Dye Works is building a new 1-story mill and steel construction factory, 209 x 215 ft., for commercial dyeing at 4203 Grand Ave. Paul Gerhardt is architect; estimated cost, \$250,000.

CHICAGO—Barrett & Barrett Mfg. Co., producer of apple products, is building a 7-story factory 100 x 61 ft. at 357 West Ontario St. Paul Gerhardt is architect; estimated cost, \$300,000.

Indiana

JONESBORO—The Indiana Rubber Co., Pearl and First Sts., is planning for the construction of a 3-story addition, 60 x 125 ft. Plans will be drawn and work commenced in the coming spring.

TERRE HAUTE—The Columbian Enameling & Stamping Co. has construction under way on a 1-story and part basement addition, to be used for enameling and other operations. Roehm Bros., 30 North Fifth St., are contractors.

Kentucky

OWENSBORO—The Indian Refining Co., Lawrenceville, Ill., is planning for the

construction of a new local distributing plant, with extensive pipe-line and pumping system for oil service, estimated to cost in excess of \$500,000.

LOUISVILLE—The Standard Sanitary Mfg. Co., Bessemer Bldg., Pittsburgh, Pa., is completing plans for the erection of its proposed local plant addition, Sixth and A Sts., to be 1-story, 56 x 375 ft., and estimated to cost close to \$100,000. It will be equipped as an enameling works. O. P. Ward, Lincoln Building, Louisville, is architect.

Massachusetts

REVERE—The Suburban Gas & Electric Co., 150 Beach St., has awarded a contract to the C. H. Tenney Co., 201 Devonshire St., Boston, Mass., for the erection of a gas holder, with auxiliary gas works, on Proctor St., estimated to cost about \$185,000.

Michigan

DETROIT—The Goodyear Tire & Rubber Co., 88 Custer Ave., has completed plans and is taking bids for extensions and improvements in its plant on Hastings St., near the Grand Blvd. Smith, Hinchman & Grylls, 710 Washington Arcade, are architects.

Missouri

KANSAS CITY—The Corn Products Refining Co. is planning for the early operation of its new local plant, in course of erection for a number of months past, and proposes to develop an extensive grinding capacity and output shortly after the first of the year. The plant will represent an investment of close to \$4,000,000.

Nevada

CALLVILLE—The West End Chemical Co. is planning for extensive developments and operations at its local borax properties for the production of colemanite and refined borax. Work will be concentrated to handle a contract calling for a minimum of 60,000 tons of colemanite and a maximum of 240,000 over a certain number of months. F. M. (Borax) Smith, San Francisco, Cal., is president of the company.

New Jersey

TRENTON—The General Chinaware Corp. has acquired the old Willits pottery, and will establish a new local plant for the manufacture of dinnerware products. Machinery will be installed at once using only a portion of the plant at the present time. The remainder will be leased for other manufacturing service.

NEWARK—The Linden Tanning Co., 440 Frelinghuysen Ave., has filed plans for the erection of an addition to its plant.

NEWARK—The Gulf Refining Co., Doremus Ave., will commence the immediate erection of a 2-story building at its plant, estimated to cost about \$60,000.

New York

CUYLERVILLE—The Sterling Salt Company of New York has contracted with Dwight P. Robinson & Co., Inc., of New York City for the design and construction of a salt warehouse and conveying equipment here.

North Carolina

MOUNT HOLLY—The Kendrick Brick & Tile Co. has plans under way for enlargements in its plant, to include the installation of new machinery, drying equipment and other apparatus. It is proposed to increase the production from 75,000 to over 100,000 bricks a day. N. B. Kendrick heads the company.

WILMINGTON—The Texas Oil Co., 701 Barrone St., New Orleans, La., has acquired a tract of property totalling about 35 acres at Wilmington, for the construction of a new oil-distributing plant. At a later date, it is proposed to use a portion of the site for an oil refinery. The company is operating a plant in Mississippi.

Ohio

LORAIN—The Briggs Chemical Co. is planning for the rebuilding of the portion of its plant, destroyed by fire, Nov. 18,

with loss estimated at about \$60,000. A. H. Babcock is president.

Oklahoma

MCALISTER—The Chamber of Commerce is developing plans for the organization of a local company for the establishment of a brick-manufacturing plant, estimated to cost about \$75,000, including machinery. A tile department will also be installed, with output of about 20,000 roofing tiles per day. The brick plant will be equipped for a daily production of 60,000 bricks.

ARDMORE—The Coline Oil Co. has acquired a tract of local property totalling about 40 acres to be used for the erection of a tank farm and oil-distributing works. The initial installation will consist of twenty-five 55,000-bbl. steel tanks.

Oregon

GRESHAM—John A. Moge has acquired a local site for the construction of a new foundry for the production of iron and other metal castings.

Pennsylvania

NEW HOPE—The American Clay Products Co. is planning to have its local plant, in course of erection for some months past, ready for service early in the coming year. Work is now under way on kilns and other manufacturing departments. The plant will be devoted to the production of vitrified brick and it is proposed to provide ultimately for an output of close to 500,000 bricks per day.

READING—The Colonial Chemical Co., Schuylkill Ave. and River Road, has preliminary plans under way for the erection of a new 2-story plant, 25 x 100 ft. High & Huber, 11 North Fifth St., are architects.

PHILADELPHIA—Philip Hauck & Son, 1237-39 North Fourth St., will soon commence the erection of an addition to their paper and paper box plant, to be 3-story, 37 x 90 ft.; and estimated to cost close to \$30,000. Harry H. Wehmeyer, 509 West Cumberland St., has the construction contract.

PHILADELPHIA—Fire, Dec. 1, damaged a portion of the plant of F. Weber & Co., 1220 Buttonwood St., manufacturers of paints, oils, chemicals and other artists' materials, with loss reported in excess of \$300,000.

Tennessee

NASHVILLE—The Farmers' Mutual Phosphate Co., 1047-48 Lemcke Annex, Indianapolis, Ind., is planning for the erection of a new plant at its properties at Centerville, near Nashville, to be known as Plant No. 3, with daily capacity of about 300 tons of phosphate, and a new mixing plant on an Indiana site. To carry out the details of the project, the company has arranged for a bond issue of \$250,000. The company is now operating a 300-ton plant at Centerville, and a 100-ton operating unit is nearing completion; it will be placed in service in January.

Texas

KINGSVILLE—The Kingsville Commission Co. is considering the erection of a new leather tannery. Plans will be prepared at an early date. Marcus Phillips is manager.

DALLAS—L. D. Lansdale and Charles A. Mangold, both of Dallas are perfecting plans for the construction of a new plant on the site of the Love Field repair depot of the government for the manufacture of sulphuric acid. A company will be organized to operate the plant, which will have an initial capacity of about 50 tons per day, and estimated to cost close to \$200,000, including machinery. One of the plant units will be devoted to the production of electrolyte acid for battery service. George A. Sprague, Dallas, is also interested in the new company.

CORPUS CHRISTI—T. B. Williams, Box 290, is organizing a new company to construct and operate a local leather tannery. Plans and details of the new plant will be arranged at an early date.

MARSHALL—The Darco Co., a subsidiary of the Atlas Powder Co., du Pont Bldg., Wilmington, Del., with headquarters at the same location, has broken ground for its proposed new local plant for the production of a new type of carbon. The initial works will have an annual output of about 6,000 tons of material, and will cost in excess of \$500,000. W. J. Webster is president.

WACO—The Waco Oil & Refining Co. is considering plans for enlargements in its oil refinery for increased capacity. It is proposed to build a new pipe line from the

Mexia, Tex., fields to the local plant. W. A. Rogers is president.

Wisconsin

GREEN BAY—The Fort Howard Paper Co. has construction in progress for a 3-story paper mill in the East Side section, to be 100 x 120 ft., and estimated to cost about \$85,000. The building contract has been awarded to the Rudolph M. Hansen Co., 113 Walnut St.

MILWAUKEE—The American Hide & Leather Co., Fourteenth St., is taking bids for the rebuilding of its local tannery, recently destroyed by fire, and will soon award contract. The works will comprise four buildings, with main structure, 200 x 300 ft., 4-story, estimated to cost close to \$700,000, including equipment. Lockwood, Greene & Co., 38 South Dearborn St., Chicago, Ill., are architects. R. A. Riker is superintendent.

Capital Increases, Etc.

THE CONNECTICUT METAL & CHEMICAL Co., New Britain, Conn., has filed notice of change of name to the Stanley Chemical Co.

THE NEWARK PAPER BOX Co., 95 Eighth Ave., Newark, N. J., has filed notice of increase in capital from \$10,000 to \$200,000.

THE SAN ANTONIO PORTLAND CEMENT Co., San Antonio, Tex., has filed notice of increase in capital from \$250,000 to \$300,000.

Ray F. Hamlin and John M. Crawford have been appointed receivers for the **AVALLON RUBBER MFG. Co.**, Akron, O.

THE SUN RIVER CHEMICAL Co., 1914 Broadway, New York, N. Y., has filed notice of increase in capital from \$300,000 to \$400,000.

THE METAL STAMPING Co., Thirteenth St., Brooklyn, N. Y., has filed notice of increase in capital from \$25,000 to \$1,000,000.

THE SOUTH PORTO RICO SUGAR Co., 62 Cedar St., New York, N. Y., is arranging for a bond issue of \$6,000,000, for general operations, expansion, etc.

THE ERIE-BUFFALO TUBE Co., Erie, Pa., has recently filed a voluntary petition in bankruptcy, with liabilities stated at \$158,092.29, and assets, \$238,816.10.

THE VACAMA MICA Co., a Delaware corporation, has filed notice of intention to operate at Waynesboro, Pa.

THE CARTHAGE SULPHITE PULP & PAPER Co., Carthage, N. Y., has arranged for a bond issue of \$600,000, the proceeds to be used for general operations, expansion, etc.

THE PIERCE OIL CORP., 25 Broad St., New York, N. Y., has disposed of a bond issue of \$2,000,000, the proceeds to be used for general operations, financing, etc.

An involuntary petition in bankruptcy has been filed against the **PULP & FIBRE PRODUCTS Co.**, Scotch Plains, N. J.

New Companies

THE FLORIDA-LOUISIANA REFINING Co., Shreveport, La., has been incorporated under Florida laws with capital of \$150,000, to manufacture refined oil products, with proposed plant in the vicinity of Jacksonville, Fla. H. C. Leete is president and general manager; and A. C. Lea, treasurer, both of Shreveport.

PETER BARAN & SONS, INC., Harrison, N. J., has been incorporated with a capital of \$125,000, to manufacture leather products. The incorporators are Arthur Read, William V. Azzoll and Peter Baran, First and Bergen Sts., Harrison.

THE BERRYMAN RUBBER & TIRE Co., New York, N. Y., has been incorporated with a capital of \$200,000 to manufacture automobile tires and other rubber products. The incorporators are H. M. Wise, E. Gibbs and E. J. Sisley. The company is represented by Lee, Aron & Wise, 7 Dey St., New York.

MILLBOND CHEMICALS, LTD., Boston, Mass., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. Julius Robbins is president; Benjamin Zakon, vice-president; and Milton H. Balch, 104 Temple St., West Newton, Mass., treasurer.

THE JORDAN PAPER BOX Co., 339 North Crawford Ave., Chicago, Ill., has been incorporated with a capital of 200 shares of stock, no par value, to manufacture paper boxes and allied paper products. The incorporators are George S. Marks, Frank H. and William R. Jordan.

THE MATTERN OIL & GREASE Co., Oil City, Pa., has been incorporated with a

capital of \$20,000, to manufacture lubricating oils, greases and kindred products. R. B. Mattern, Oil City, is treasurer.

THE LAMSON ASPHALT & CHEMICAL Co., New York, N. Y., has been incorporated under Delaware laws with capital of \$150,000, to manufacture chemicals, dyestuffs and kindred products. The company is represented by the United States Corporation Co., 65 Cedar Street, New York.

THE CONNECTICUT HARD RUBBER Co., 600 State St., New Haven, Conn., has been organized under state laws to manufacture rubber products. J. A. Moffitt, 25 West 45th St., New York, is president; and A. A. Smith, 96 Howard St., New Haven, secretary and treasurer.

THE KUYKENDAL CHEMICAL Co., Columbia, S. C., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are C. M. and F. R. Kuykendal, both of Rock Hill, S. C.

THE WALLABOUT PAPER SPECIALTIES CORP., Brooklyn, N. Y., has been incorporated with a capital of \$30,000, to manufacture paper products. The incorporators are J. Karper, L. and J. Blazer. The company is represented by Samuel Blazer, 52 Wall St., New York.

THE UNITED GULF STATES OIL COMPANIES, INC., New York, N. Y., has been incorporated under Delaware laws with capital of \$10,000,000, to manufacture petroleum products. The incorporators are H. E. Ellis, J. L. Cunningham and W. H. Mayhar. The company is represented by the Charter Service Corp., 149 Broadway, New York.

THE M. C. S. CHEMICAL CORP., Jersey City, N. J., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are E. Burke Finnerty, Morris B. Dorman and Frank W. Hastings, Jr., 15 Exchange Pl., Jersey City.

THE MT. JEWETT FIRECLAY Co., Bradford, Pa., has been incorporated with a capital of \$50,000, to operate fireclay and other clay properties. R. G. Vogel, Bradford, is treasurer.

THE NORTON LEATHER Co., Salem, Mass., has been incorporated with a capital of \$50,000, to manufacture leather products. Michael H. Norton is president; and Joseph P. Norton, 100 School St., Salem, treasurer.

THE FRANCO-UTAH OIL Co., Salt Lake City, Utah, has been incorporated under Delaware laws, with capital of \$5,000,000, to manufacture petroleum products. The incorporators are D. H. Gustaveson and J. W. Musser, both of Salt Lake City. The company is represented by the Corporation Service Co., Wilmington, Del.

THE ESSEX PRODUCTS Co., Main and Terry Sts., Belleville, N. J., has been incorporated with a capital of \$125,000, to manufacture chemicals and chemical byproducts. The incorporators are Howard R. Lewis and Harry V. Fisher.

THE CONSOLIDATED STAMPING & MFG. Co., Gaylord and Plymouth Sts., Detroit, Mich., has been incorporated with a capital of \$500,000, to manufacture stamped metal and other metal products. The incorporators are Archibald A. Hitchcock, Harry M. Coates, and Robert T. Carr, 54 Tyler Ave., Highland Park, Mich.

THE RED DIAMOND CHEMICAL Co., Wilmington, Del., has been incorporated with a capital of \$100,000 under state laws, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Service Co., Wilmington.

THE GREAT EASTERN REFINING CORP., Huntington, W. Va., has been incorporated with a capital of \$200,000, to manufacture refined oil products. The incorporators are Fred W. Dulancy, John F. Grossenbach, both of Huntington; and T. H. Gillman, Ashland, Ky.

THE EVERLASTING ROOF TILE CORP., Brooklyn, N. Y., has been incorporated with a capital of \$50,000, to manufacture clay roofing tile and other burned clay products. The incorporators are N. N. Payne, D. J. Horgan and T. P. Killilea. The company is represented by Fitzgerald, Stapleton & Mahon, 25 Broadway, New York.

THE FRYE CHEMICAL Co., INC., Montclair, N. J., has been incorporated with a capital of \$50,000, to manufacture chemicals and affiliated products. The incorporators are Walter T. Lindsay, John A. Bennett, and A. C. Kotze, 460 Bloomfield Ave., Montclair.

THE MISSISSIPPI OIL Co., Wilmington, Del., has been incorporated under state laws with capital of \$2,000,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE GREAT EASTERN CHEMICAL Co., Wilmington, Del., has been incorporated under state laws with capital of \$50,000, to manufacture chemicals and chemical byproducts. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE SOUTH BEND OIL REFINERIES, INC., South Bend, Ind., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are W. J. Kennedy, Karl G. King and J. L. Nolan, all of South Bend.

THE SALEM FLINT GLASS Co., Salem, W. Va., has been incorporated with a capital of \$10,000, to manufacture glass products. The incorporators are H. L. Bee, B. S. Bischoff and F. R. Davis, all of Charleston, W. Va.

THE VERSIL CHEMICAL Co., New York, N. Y., has been incorporated with a capital of \$5,000, to manufacture chemicals and chemical byproducts. The incorporators are H. and M. Spatt and A. L. Lazarus, 154 Nassau St., New York.

THE ZANTHONE MFG. Co., Philadelphia, Pa., is being organized under state laws to manufacture cellulose products. The incorporators are John C. Dempsey, J. Harold Felton and Frank Devlin. Application for a state charter will be made on Dec. 12. The company is represented by Porter, Foulkrod & McCullagh, 1106 Commonwealth Bldg., Philadelphia.

THE TRINITY RUBBER PRODUCTS Co., 35 Drift St., New Brunswick, N. J., has been incorporated with a capital of \$25,000, to manufacture rubber products. The incorporators are Charles H. Durham, Ernest L. Daniels and John F. Westburgh.

THE SEYDEL CHEMICAL Co., Nitro, W. Va., has been incorporated with a capital of \$1,500,000, to manufacture chemicals and allied products. The company is headed by Herman Seydel, head of the company of the same name now operating at 86 Forrest St., Jersey City, N. J., and Richard S. Bicknell, Nitro.

THE SECURITY PETROLEUM & REFINING Co., New York, has been incorporated under Delaware laws with capital of \$100,000, to manufacture refined oil products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 26 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Number 25

Talking

And Working

A GENTLEMAN of the Central West who has been traveling around the country a good bit in the past few weeks expresses the conviction that Americans have got into a habit of talking too much. Nearly everywhere he went he found a "convention" in session or in prospect, and some of these conventions he attended. The chief aim of the speakers at the conventions was to tell their hearers what was wrong with the United States and the world generally and what other people had to do in order to make things right for us. The same gentleman had been in Europe for a couple of months and he draws a comparison unfavorable to us, saying that the people of France, Belgium and Germany are working hard, while the British are gradually getting to work.

Of course, there are conventions and conventions. It is one thing to tell a gathering of farmers what the gold bugs are doing and another thing to tell what ought to be done to potato bugs. One is constructive and destructive (to the potato bugs), while the other is not even destructive. At a convention of engineers those in attendance get ideas, or should get ideas, whereby when they get home they can do better work. When a convention of business men or farmers is told the various things that are wrong with the United States and numerous other countries and how times will not be good until things are righted, are those in attendance fortified to do harder and better work when they get home?

This is a sort of mob psychology. One does not need to attend meetings or conventions to observe it. We do not escape the talk by avoiding reading the *Congressional Record*, for we encounter it in the daily newspapers, on the street, practically everywhere. It is another form of "the world owes us a living," for it requires no close analysis to see that much of the talk is motivated by the idea "If the rest of the world would just behave itself, I could make some money."

At bottom most of the thoughts expressed are selfish. There is the talk about railroad freight rate reductions. We want to buy our goods more cheaply and have a broader market for the things we want to sell. Before the war the talk was that freight rates ought to be advanced, because we wanted railroad orders. We want conditions in Europe to get settled so that we can sell our goods to Europe. But just think of what the rest of the world could say about us along that line! The rest of the world owes us in funded debt about eleven billion dollars and there is in addition four billion or more of unfunded balance in favor of the United States, making a total of fifteen billion or more, and then men are shouting that they want the rest of the world to get in shape to buy our goods. The rest of the world would like us to provide an opportunity to pay something

against what they already owe us. They have sent us this year about half a billion dollars in gold and the gold reserves of the Federal Reserve system are now nearly equal to the combined gold reserves of all other countries, while people in the United States are explaining when they can get listeners that the other countries ought to stabilize their currencies.

Undoubtedly we are talking too much along lines that do not get the talker or the hearer anywhere, but rather encourage a disposition to wait until something turns up, until freight rates are reduced or the French army is disbanded or the German indemnity is paid or Russia gets on its feet or the federal taxing system is revised again. If we really must talk let us talk about working. If we can't find work of the kind we used to do, let us think up something new. The movie shows seem to be getting along quite well. They aim to offer the public something new each week.

We Congratulate

Mr. Dawes

THE FIRST budget of the United States Government has been presented to Congress. In many particulars it is an admirable document. And in one particular scientists and engineers should be especially pleased with it—the treatment which has been accorded the technical and scientific work of the federal departments.

The effort in drafting the budget has been to curtail expenses, an effort which every taxpayer will strongly commend. But apparently the effort to reduce the cost of government has not been rashly and recklessly undertaken to the detriment of really worth-while projects. In fact there seems to have been a real distinction made between apparent and real economy in the reduction of expenditures. Of all the technical and scientific bureaus, very few have suffered reduction in the appropriation recommended for their scientific investigations and their constructive engineering effort. There have, indeed, been actual increases recommended for most of these institutions.

For the Bureau of Mines, Patent Office, Geological Survey, Bureau of Standards, Chemical Warfare Service and several others, the increases recommended to Congress for total appropriations are from 5 to 25 per cent greater for the coming fiscal year than the sums which have been provided during the current year. The increases thus provided are intended in some cases for increasing salaries of the scientific staff, notably to increase the standard of salaries paid to the senior members of the staff. Certainly this is a move in the right direction, in order that the quality of the work done by these institutions may not suffer indefinitely because of the wholly inadequate salary scale which has prevailed in many lines. A few new and much needed investigations are also proposed for important scientific and industrial problems of wide interest.

Chicago Business Men

Clearing Labor Situation

EVENTS during the past fortnight indicate, very clearly that the tide has definitely turned in labor circles. No one set of circumstances has more strongly shown the revulsion against unfair practices on the part of labor than the results obtained by the Citizens' Committee to enforce the Landis award in the building trades, covered in our editorial in the Nov. 23 issue. Chicago, long the stronghold of labor agitators and malicious strike promoters, will harbor these business criminals no longer. Even the more recent strike of the stockyards workers is broken by hordes of hungry men who seek work in the face of physical danger. Another week should mark the end of this phase.

The Landis Award Committee, incorporated in Illinois "not for profit," has now accomplished many things. Fifty-five subdivisions of the Association of Commerce have pledged solid support. The chairman has signed a blanket insurance policy for several million dollars to protect property owners who observe the terms of the award from the vandalism of wrecking crews. Pledges have been given by sixteen mortgage banks that loans will be made only where the Landis award is being followed. A million-dollar loan has recently been denied a big subdivision contractor because of his refusal to abide by the rules.

The carpenters' union situation has been settled by the committee. This union failed to comply with the working conditions and wage scale laid down by Judge LANDIS, and the open shop has been definitely established. A large number of carpenters, more than are actually needed, have deserted the union band-wagon to work for \$1 per hour rather than starve.

The committee is calling in violators of the award as rapidly as the scouts can discover them. Of 800 different jobs visited to date, 102 violators have been discovered. On the other hand, the contractors are not allowed to cut wages below the amounts fixed by Judge LANDIS. No mechanic on award jobs need fear that his wages will be slashed below the rate.

All fair-thinking citizens are behind the work. They know the committee is acting for them as a contract enforcer, not as a contract breaker. Arbitrary unionism is dying in Chicago. The year 1922 will be a hard one for strikers. Making the award stick is not only a great thing for Chicago. Precedents are being established that will have a far-reaching effect for better business and happier communities over the whole country.

Organization as a

Factor in Research

LATELY we read a report of the Committee of the Privy Council for Scientific and Industrial Research of Great Britain which consisted in a statement of pounds, shillings and pence expended under various heads. Of course we must keep accounts, and watch expenditures, but it is often the habit of the layman to call for figures in regard to the progress of work in laboratories when it is impossible to tell it in figures. Statements of costs may be the poorest possible index of the progress of research. We know of a laboratory, an excellent and fruitful institution, that was nearly upset by a complicated cost system that required of every member of the staff that he record every minute of his time, and charge it to some specific account. This was about as sensible as to ask a commercial traveler to work out his expense account while he is selling goods.

In the British report quoted, the Advisory Council made a supplementary memorandum which met the difficult task of explanation and comment with ability; but the point we desire to emphasize in this connection is that, while expenditures are needed for the prosecution of research, there is a factor of still greater importance which is a far better indicator of progress than a list of expenditures, and that is the organization of the laboratory.

This is the point we want to emphasize. A research laboratory must be a living thing; an organization within itself. We cannot establish it even by selecting men according to their past performances. They must achieve the art of working together. One of the greatest mistakes is to hold that men produce better if they dislike one another and each one wants to get ahead of his fellows in performance. Explanations are necessary as work proceeds, and the habit of working together and of understanding one another among members of a staff makes explanations not only possible, but short. Otherwise an immense amount of unnecessary work is done to no effect, because the man who does it fails to understand its aim.

There is a curious psychology in organization. The greater the number of persons that are engaged in an organization the less is their common understanding. It stands to reason that what A knows is only partly shared by B, and if C joins the group there is still less that he shares with both A and B. Every added person decreases the measure of understanding common to all. But when the habit of working together is formed they can make their thoughts known one to another with little or no effort. A mere hint from A will illumine B and C, and under this joint illumination a new power arises. Our inhibitions are brushed away. We venture to propose things and to do things that theretofore we were too shy, too bashful, too lazy, too inert to propose. With this quality, resolution becomes contagious, and when every member of a laboratory staff is resolved to achieve a definite result and this resolution grows so strong that the quality of faith is added to it, then we are not indulging in idle vagaries when we hope for results. They come bounding along, provided, of course, those who constitute the staff are not idle dreamers.

Peace-Time Uses

For Gas Bombs

EVERY time we read a press account of the riotous actions of leaderless mobs, men or women, we can't help thinking how salutary would be the effect of a little tear gas judiciously distributed. Mobs are hard to handle because they are without leaders and cannot be appealed to by reasonable means. The whole history of mob violence, in this or in other countries, shows how difficult it has been to handle them even when met by force or resort to violent means. Hitherto it has been necessary to call upon the police or the military, with resulting casualties that are deplored by even those in authority. But we now have a weapon that should be even more effective, not only because it will disperse mobs, but because one experience with tear gas is likely to be remembered for a long time and thus deter the potential mobber from engaging in that pastime again. The physical effect would only be temporary, but psychologically a dose of gas would have a beneficial and lasting influence. It seems to us that the time is ripe for the commercial exploitation of this method of controlling unruly citizens.

Engineers Honor Marshal Foch

IN CONFERRING upon Marshal FOCH honorary membership in the four national institutes of civil, electrical, mechanical and mining engineering, those bodies gave a fitting touch to the close of a strenuous visit to America by the recipient. Probably no guest from a foreign country has ever received more honors at the hands of his hosts, but it was particularly appropriate that the Marshal should have been recognized by engineers. As stated by Colonel PARSONS, commander of the Eleventh Engineers in France, in an introductory address, Marshal FOCH "directed a greater mass of human energy than any other man has ever done," and consequently had exhibited in the highest degree the qualities of an engineer, more particularly because he "successfully directed this mass for the highest uses of mankind." In acknowledging the honor bestowed upon him, the Marshal said that "it was due largely to the engineers and the engineering industries that the war was brought to a successful close," thus recognizing one of the most potent forces in the war, though perhaps it was and still is popularly the least recognized and appreciated. In honoring Marshal FOCH, the engineering societies honored themselves and gave a further impetus to the recognition of the importance of engineering.

Chemists and Time Clocks

WE REFERRED in our issue of Nov. 23 to the fact that in the Navy Department chemists are rated as artisans on a per diem basis. We have since learned that under a ruling made in September, on recommendation of a wage board consisting of a naval officer, a clerk from the office of the Secretary of the Navy and a representative of the American Federation of Labor, all technical employees and day laborers are now engaged on a per hour basis.

What is the use of this sort of tumblebug management? Why try to make head work look as much as possible like hand work? The man whose business it is to think must have freedom to think. We can all march in lock-step under compulsion—if we have our legs intact—but we can't think in lock-step and develop the thoughts and ideas that add to human progress and which are the things that are wanted of us.

We know one chemist who does his best work, thinks his best thoughts, while shaving in the morning. That, however, is no reason why "the shaving hour" should be made sacred to chemists or that the American Federation of Labor, which has nothing to do with the subject, should recommend time-and-a-half or double for the chemists' matutinal lathering and scraping. The chemist is a professional man. He may have remarkable manual dexterity or be singularly lacking in this respect and require laboratory assistants to do his work better than he can. What he is wanted for is his thinking, and he has had to develop his habits of thought in his own way. If he had not done this, he would not be wanted as a chemist.

The time clock is a useful invention to check off the work of men who predetermine their conditions of employment. In a laboratory, except for laboratory helpers, it is likely to be the most expensive piece of apparatus in the establishment. Thinking is not only work, but about the most difficult hunting of the present day is to find men who can and will think. Then why

should we equip the position of a thinking man with hindrances which discourage thought?

We have great admiration for the honorable Secretary of the Navy as a man, but we wish he would read this. He can't pay much for chemists, and he needs them; needs good ones. Therefore he should not make such an absurd ruling no matter what a board of incompetent advisers may think. Often the whole issue between a positive and a negative result depends on whether the chemist at work on the problem takes a walk around the block by himself in the fresh air or not. There's too much unnecessary commanding and forbidding going on, and the cost of it is a halt to progress.

Chicago Chemists Show Progress

RECENTLY it was our good fortune to attend one of the regular meetings of the Chicago Section of the American Chemical Society, and we were struck with a plan of organization that seems to have worked successfully and which may be adapted to other large sections of the Society. Attendance at the monthly meetings of the Chicago Section has increased to such an extent that it became necessary to devise some means whereby a larger number of individuals could participate in the proceedings and particularly whereby the younger members could be encouraged to express themselves. At the suggestion of Dr. PAUL N. LEECH, chairman of the program committee, the Section adopted a plan of holding four group sessions following the principal program of the evening. Each month the majority of the members who attend the general session remain to participate in group meetings devoted to various phases and branches of chemistry. Here the everyday problems of the members of the groups are discussed freely and intimately. The whole scheme has been remarkably successful and is typical of the ingenuity and initiative that frequently characterize our Western friends. Precedent and formality are waived if they impede progress. The example is worthy of emulation in other sections where conditions warrant.

A Loss to the Cause Of Leather Chemistry

IN THE death of ARTHUR H. GALLUN, of Milwaukee, prominent in the manufacture of leather, the cause of chemical research in this industry has suffered a serious loss. With exceptional vision he supported vigorously the application of chemistry to the production of leather. For years he struggled to awaken in his fellow tanners a realization of the value and power of fundamental chemical research, but the time was not ripe and his preachments fell upon ears that refused to hear. Undaunted, he generously endowed research work at Columbia University, the results to be published freely so that the industry might see for itself the value of applied chemistry. With the same object in view, he inspired his own laboratories to contribute to the development of the science and assisted in the organization of the Leather Division of the American Chemical Society. At the time of his death he was trying to persuade the leather industry to establish at Columbia University a department of leather chemistry that should become second to none in the world. We regret his passing because the leather industry sorely needs the pioneer work he was doing so well. It will yet bear fruit, but not as soon as if he were here to give it his wise, far-seeing and energetic support.

American Institute of Chemical Engineers, Baltimore Meeting, December 6-9

Papers Presented at the Annual Winter Meeting Stress the Relation of the Chemical Engineer to the National Defense—Government Plants at Edgewood and Annapolis and Many Baltimore Chemical Industries Are Inspected—Election of Officers

BALTIMORE, during the four days Dec. 6-9, was the scene of the fourteenth annual meeting of the American Institute of Chemical Engineers. The many chemical industries of the vicinity and the close proximity to Edgewood Arsenal, the Naval Academy at Annapolis, and the Disarmament Conference in session at Washington served to give an appropriate background to the discussion of the theme of the meeting, which was "Chemical Engineering and the National Defense." An unusually large proportion of the Institute's membership was on hand to contribute to the symposium on this important subject and incidentally to enjoy the pleasant arrangements and entertainments provided by an enterprising local committee, headed by a very efficient local chairman, Albert E. Marshall.

During the first business session of the convention, which was called promptly to order on Dec. 6 by President David Wesson, many important items of the Institute's business were transacted. Following the reading of a number of reports by the secretary, Dr. John C. Olsen, and others, Dr. Arthur D. Little presented the final report of the committee on chemical engineering

education. This committee has made a most comprehensive study of the courses offered by the universities and colleges of the country and has prepared a report which strongly emphasizes the need for reorganizing existing methods of instruction in chemical engineering. The report points out the extreme difficulty in obtaining comparable data in the seventy-three institutions which teach this subject. This was due not only to the extraordinary number of subjects included in the chemical engineering courses, but also to the divergence in the weighting of courses among the various universities. In referring to the 210 subjects being taught, the committee was of the opinion that more than half were unnecessary. For instance, it is somewhat difficult to justify 49 subdivisions of chemistry and 35 of mechanical engineering.

The committee tabulated fourteen recommendations and conclusions which were as follows:

- (1) There is an undesirable multiplication of subjects included in the chemical engineering courses.
- (2) Wherever possible intricate subdivision of subjects should be avoided.
- (3) A thorough grounding in chemistry and physics is essential.
- (4) An effort should be made to standardize the naming of courses.
- (5) There

should be less divergence in weighting courses. (6) Instruction in civil engineering, sanitary engineering and electrical engineering (beyond the fundamentals) might well be omitted. (7) Specialization by industries is considered advisable in the usual 4-year curriculum. (8) Small institutions where locality and special conditions call for training in certain industries may, however, be considered as exceptions to this rule. (9) Poor English and inaccurate report writing are recognized as prominent points of weakness in most engineering graduates. (10) Sources of information should be studied during the student's senior year. (11) The course in chemical engineering should best follow three years' preparation in mathematics, economics and the sciences. (12) The difficulties of chemical engineering as a profession should be emphasized. (13) Courses should be arranged to give a professional degree to chemical engineers completing satisfactory work in the industries. (14) The use of students as instructors, even in elementary courses, should be deprecated.

It was voted that the committee's report be printed immediately by the council and that later the Institute should arrange to devote a meeting to the consideration of this subject, in which meeting representatives of the educational institutions might participate.

ATMOSPHERIC POLLUTION

Prof. James R. Withrow presented the report of the committee on atmospheric pollution. He called particular attention to the notable work of Dr. P. J. O'Gara of the American Smelting & Refining Co., Salt Lake City, Utah, and stated that the committee had urged Dr. O'Gara to publish the results of his investigations at the earliest possible date. In view of the prospective publication of the results of this and other extensive smelter fume investigations, the committee recommended that the Institute adopt no program of research, but rather hold itself in readiness to cooperate with the chemical manufacturers' associations and others interested in legislation and other methods

of regulating atmospheric pollution. It was further urged that all chemical manufacturers recognize the far-sighted policy of settling promptly and out of court all just claims and that they fight to the limit all unjust claims because of the far-reaching damage which may result from precedents accidentally established through erroneous court decisions.

STUDENT CHAPTERS AND ANNOUNCEMENT OF NEW OFFICERS

Prof. A. H. White reported for the committee on student chapters. He submitted an amendment to the constitution of the Institute which provided for establishing student chapters in universities of recognized standing. The proposed plan is somewhat similar to that of the American Society of Civil Engineers in that while the student branches are recognized, there is no provision for student membership. According to regular procedure the amendment is to be sent out to the members for their approval.

Under the program of stated business the proposal was made to change the society's name to "The Institute of Chemical Engineers," but following a very eloquent and patriotic appeal by C. Burrows Morey, it was unanimously voted to retain "American" in the Institute's name.

Hugh Kelsea Moore, in discussing the method of nominating officers, protested against the appointment of a nominating committee and suggested that the method outlined in the Institute's constitution should be followed in future elections. Prof. Ralph H. McKee then announced the result of the canvass of ballots for next year's officers, which was as follows: Henry Howard, president; Albert W. Smith, first vice-president; Hugh K. Moore, second vice-president; Harlan S. Miner, third

vice-president; John C. Olsen, secretary; F. W. Frerichs, treasurer; Charles F. McKenna, auditor. The new directors elected were William H. Bassett, Arthur C. Langmuir and Alfred H. White.

The only address to be given during the first session was by L. W. Wallace, executive secretary of the Federated American Engineering Societies, who spoke of the work this organization had done during the first year of its existence and then outlined some of the important activities which are being contemplated. He especially stressed the need for an organized campaign in behalf of the Patent Office. The deplorable conditions existing there are causing delays of serious consequence to industry.

VISITS TO CURTIS BAY INDUSTRIES AND EDGEWOOD ARSENAL

During the afternoon an excursion was made to the chemical industries at Curtis Bay. The plant of the U. S. Industrial Alcohol Co. was inspected and the visitors witnessed the operation of stills which were producing 95 per cent alcohol at the rate of 60,000 gal. per day. At the plant of the Davison Chemical Co. experiments were shown with silica gel to demonstrate its use in the making of sulphuric acid and ice, in drying air for blast furnaces and in refining gasoline and petroleum distillates. On the return trip the chemical engineers stopped at the plant of the American Refractories Co., where special magnesite and chromite bricks were being manufactured.

Approximately two hundred members of the Institute and of the Maryland Section of the American Chemical Society arrived at Edgewood shortly after 10 a.m. Dec. 7. Special facilities had been provided for a thorough inspection of the laboratories and manufacturing plants of the Arsenal. Especial interest was manifested in the chlorine, phosgene and chlorpicrin plants as well as in the factory which is turning out a daily production of 100 gas masks of the latest approved type.

Brigadier-General Amos A. Fries, chief of Chemical Warfare Service, addressed the party at luncheon. He declared that an effort was being made to stampede the Disarmament Conference against chemical warfare. The proponents of this propaganda include a number of well-meaning sentimentalists and so-called peace advocates, but a considerable proportion of them are to be recognized as self-interested enemies of the chemical industry. Chemical warfare, said General Fries, is the natural means of defense of a scientific people and, he declared, causes less permanent disability than any other weapon of warfare. Quoting statistics from the Surgeon-General's office, he showed that but 27.3 per cent of the men admitted to the hospitals during the late war suffered from gas injuries alone, that deaths directly attributable to gas were only 2 per cent of the total fatalities, and furthermore that the man injured by gas had twelve times as many chances for recovery as the man whose wounds were caused by shells or high explosives.

After the address by General Fries the party was taken to the testing range, where a demonstration of various gases and smoke materials was staged. The visitors, among them a number of ladies, stood on a slight hill and to their left, behind a rise of ground, were the various implements of chemical warfare. The first to be demonstrated was the Livens projector, which was used to lay down a dense cloud of smoke caused by the bursting of titanium tetrachloride projectiles.

Stokes mortars were fired next, the shells being loaded with phosphorus. As they burst down the field throwing bits of fire far out into the air, another huge smoke cloud was raised. Artillery firing of 75-mm. gas shells followed, in which an attempt was made to demonstrate the accuracy of this method. The toxic smoke candles and hand grenades containing gases gave the visitors an idea of some of the post-war developments in chemical warfare. The grenades, which were filled with tear gas, were thrown so that the gas would drift away from the crowd. Some one, however, tossed one to the windward and as the gas settled over the spectators, most of them, weeping copiously, hurried away from the scene.

PRESIDENTIAL ADDRESS

The symposium on Chemical Engineering and the National Defense was opened by President Wesson on the morning of Dec. 8. Prof. Alfred H. White, who had been prevented from delivering his address on "Explosives and Fertilizers" at the earlier meeting, briefly summarized the principal points in his paper. Because of the importance of the subject and its treatment by Prof. White, arrangements have been made to have the address published in its entirety in an early issue of CHEMICAL & METALLURGICAL ENGINEERING.

The presidential address of Dr. Wesson dealt with the Institute of Chemical Engineers and the national defense. In his opening remarks President Wesson said:

In the selection of meeting places for the Institute during the past years an effort has been made to have papers presented which bear definitely on the industries visited. Thus at Savannah we had the industries of the South and the cotton oil industry in particular. In Canada we had the products of the forests and mines and the manufacture of paper stock. At the New Orleans and Louisiana meeting we had sugar, salt and sulphur. At Detroit the automobile engaged our attention, and now, assembled in Baltimore with its vast chemical industries, the proximity to Edgewood Arsenal and the Disarmament Conference, it seems that the proper keynote to our meeting should be "Chemical Engineering and National Defense."

The speaker then traced the development of warfare, particularly in relation to chemistry and the part which chemical engineering plays in the national defense. In this connection he pointed to the accomplishments of the Institute:

A glance through our membership roll will show the parts which our members take and have taken in building up the many industries of our country and keeping them on a sound economic basis. A study of these varied industries will show that while developed fundamentally for the beneficent demands of peace, they have proved towers of strength in time of war.

Founded as it was with high ideals based on a sound code of ethics, the Institute has developed slowly but surely along conservative lines. It has now outgrown its swaddling clothes and with a broad-minded interpretation of its membership rules has increased the number of its members to a point where it has become a body of considerable influence in technical, educational and national affairs. With all of the best minds of our profession co-operating to advance the industries of our country so that in its chemical resources it may be second to none, the Institute has a great field of usefulness before it, and will play a most important part in the national defense of the future.

THE IMPORTANCE OF RESEARCH

A paper by Dr. Raymond F. Bacon on "The Future Warfare" and another by Maximilian Toch entitled "Chemistry and the Next War" served to show the future possibilities offered by the development of chemical warfare. Both speakers emphasized that these

developments would come only through intensive research. Dr. Bacon's statement was as follows:

One of the greatest lessons of the war, which so far has gone almost unheeded, was that large-scale research can solve practically any problem. We had in Washington a research organization in which were gathered many of the best brains of the country. That research organization was able to solve every problem put up to it by those in command of the military forces. It showed that things which seemed to be impossible to do could be done and done in a rather short time by research backed by adequate resources of brain power and apparatus. The total cost of that organization, put together and run admittedly not at the highest efficiency in the stress of war time, was about two million dollars, and for this comparatively small sum no one could deny that results were obtained which did more toward winning the war than any two hundred million dollars spent in other ways.

If this government would efficiently spend a few million dollars a year on war research, methods would surely be devised which would make us absolutely safe from attack without the necessity of maintaining such extensive army and navy organizations as at present.

Harrison E. Howe further stressed this important subject in his address on "Fundamental Research in Conservation and Defense."

"The warfare of the future," said Mr. Howe, "seems sure to be of a decidedly different character than that which was known previous to the World War. Those concerned with our defense in the future are pretty sure to think in terms of molecules, atomic structure and perhaps atomic energy, rather than in millions of men and fleets of battleships. Our most potent defense, therefore, lies in knowledge to be acquired only through continued research."

In concluding his paper the speaker summarized his argument with the statement that "a certain amount of waste can be eliminated in industry, natural resources can be conserved and broad national interests forwarded to a great extent by the proper application of our present chemical knowledge. Our full duty as chemists and chemical engineers cannot be done, however, unless we are able to engage upon programs of serious fundamental research."

THE KEY POSITION OF THE CHLORINE INDUSTRY

Dr. Benjamin T. Brooks presented a well-prepared paper dealing with the chlorine industry as an essential factor in our national defense. The fact that this industry is not in a critical position, such as the dye and organic chemical industry, perhaps explains why there has been no organized publicity calling attention to its vital relation to the manufacture of toxic gases. He cited that the United States military program of Aug. 12, 1918, called for the daily production of 646 tons of gas, a predominating proportion of which was to be made from chlorine. Among the war-time uses for chlorine other than in the manufacture of gas, Dr. Brooks called attention to the production of bleaching powder for the manufacture of chloroform and for preparing the well-known Dakin solution and for sterilizing drinking water in the camp and in the field, and also the use of chlorine in manufacturing several of the best smoke-screen materials, tetrachloride of tin, titanium tetrachloride and silicon tetrachloride.

The chemical products made by Edgewood Arsenal and its affiliated plants consisted of phosgene, chlorpicrin, mustard gas, diphenylchlorarsine, brombenzylcyanide, chloracetophenone, "D.M." titanium tetrachloride and tin tetrachloride, all of which substances require chlorine in their manufacture.

WASHINGTON'S MONUMENT AT MT. VERNON PLACE, BALTIMORE

This was the first monument to be erected by any state to the memory of George Washington.

One factor in the situation, which is by no means the least important, has been the improvements in the methods of transporting liquid chlorine. In this connection the speaker said:

The small cylinder, containing 100 to 150 lb. of liquid chlorine, with which you are all familiar, was developed in Germany, but the tank car, holding 15 tons, and the large drum, holding 1 ton, of liquid chlorine are American developments. The first 1-ton containers were made in 1910, but their first extensive use came during the war period, when these containers were employed for shipping liquid chlorine to France. A special form of tank car, carrying chlorine in these 1-ton containers, has been developed, this method of transportation having all of the advantages of a 15-ton tank car, is comparably safer, and since these drums are removable from the car, they render storage and handling of liquid chlorine in large quantities a very simple matter. Another factor in the increased production of liquid chlorine is probably the improved liquefying process, consisting in the entrainment of chlorine in a falling column of concentrated sulphuric acid, by which means it is compressed under the necessary pressure. This simple method was given to the government by the Mathieson Alkali Works through Colonel C. F. Vaughn, and subsequently has been installed in other industrial plants.

SOME PREVENTABLE LOSSES IN THE CHEMICAL INDUSTRY

John S. Spicer, chemical engineer for the Pennsylvania Department of Labor and Industry, in an interesting communication called attention to the serious drain on man power and the increasing losses caused by industrial accidents. Reports from approximately one thousand chemical plants in Pennsylvania show that during 1920 there were sixty-two fatalities and that during the first 9 months of the current year fifty-eight lives were lost in these same plants. In other words, the indications are that the chemical industry of Pennsylvania, in spite of the fact that the number of workers is less, will probably experience a large increase in the number of fatal accidents. As an indication of the direct monetary loss, it is of interest to know that the compensation which must be paid this year by the chemical manufacturers of Pennsylvania will amount to almost a third of a million dollars. Furthermore, it is estimated that these industrial accidents entail a loss of 36,000 man-days and thus prevent the manufacture of approximately two million dollars worth of chemical

products. Considering the fact that these figures represent the losses incurred in but a single state, it is obvious that the engineers must co-operate to make the chemical industry less dangerous to the employee and more profitable to the management.

MEETING AT JOHNS HOPKINS UNIVERSITY

Following a pleasant afternoon spent in an inspection of the grounds and buildings of the Naval Academy at Annapolis, the chemical engineers returned to Baltimore for a joint meeting at Johns Hopkins University with the Maryland Section of the American Chemical Society. Dr. J. C. W. Frazer delivered a popular address on carbon monoxide and its oxidation at room temperatures by means of a catalyst. Although the army gas masks used during the late war did not provide adequate protection against this gas, there are a number of reasons why carbon monoxide is impractical as a poison gas. It is not nearly as toxic as most war gases, and because of its density it readily diffuses. It is therefore difficult to maintain a lethal concentration in the field. Its critical temperature is such that it cannot be liquefied, and hence is not easily transportable. However, carbon monoxide is produced by incomplete combustion both on the field and in the battleship and submarine and therefore adequate protection must be provided against it. One of the possible protective measures was the development of a catalyst which would oxidize carbon monoxide at room temperature with oxygen from the air. In order to serve satisfactorily in the canister of a gas mask, the reaction must proceed to completion in a fraction of a second.

Dr. Frazer outlined the work which has led to the development of a particularly efficient catalyst.¹ This material consists of an intimate mixture of extremely finely divided manganese dioxide and silver oxide, although it has been found practical to replace the silver oxide with copper oxide. The physical condition of the catalyst, its porosity and moisture content are factors greatly affecting its efficiency. When used in the canister it has been found desirable to place a layer of calcium chloride or similar drying material immediately ahead of the catalyst.

Prof. R. W. Wood gave an interesting address on "Ultra-Violet Light" and presented some remarkable experimental demonstrations. One of the most practical applications of ultra-violet light in warfare was the development of a signaling instrument using invisible rays which focused on a phosphorescent screen. The electric searchlight and reflector method which had previously been used was unsatisfactory because it was visible and therefore likely to attract enemy fire. The screen used in the instrument devised by Prof. Wood was coated with barium-platinum sulphide on which the rays of ultra-violet light produce a very noticeable green phosphorescence. Other military uses for the invisible "lights" were for guiding ships in convoys, for identifying airplanes which had been camouflaged to represent those of the enemy, and in detecting secret communications which had been written with invisible ink.

FINAL BUSINESS SESSION

The report of meeting of the council was discussed at the last business session of the convention during the morning of Dec. 9. The proposal of the Detroit mem-

bers that the Institute establish local sections was not approved in its entirety, although the council recognized the right of such sections to exist informally as long as their actions were not binding to the Institute. Prof. Badger's communication pointing out the inadequacy of the present published sources of chemical engineering abstracts was referred to a committee consisting of Messrs. Badger and Howe.

A resolution calling attention of Congress to the critical position of the domestic organic chemical industry and urging that adequate protection be given this industry was introduced by Prof. Ralph H. McKee and was passed unanimously. A second resolution informing the American delegation to the Disarmament Conference, the advisory committee thereto and the members of Congress of the imperative necessity of maintaining our Chemical Warfare Service was presented by Dr. Raymond F. Bacon and unanimously adopted.

The name of Brigadier-General Amos A. Fries was proposed for honorary membership in the Institute and the council was instructed to present his name to the members for immediate consideration.

Robert M. Yerkes, chairman of the information service of the National Research Council, reported that the council has organized a free information service which is acting as a clearing house for scientific and engineering interests. The purpose of this informational bureau is to facilitate research in all of the natural sciences and in the application of their results, and to render available to all who are intelligently interested in science and its applications reliable information about methods of research, research results, etc. Chemical engineers are cordially invited to avail themselves of this aid as they have occasion.

NEW PRODUCTS FROM PETROLEUM

Prof. J. H. James of Carnegie Institute of Technology read an original paper on the subject of "Some New Petroleum Products," starting with petroleum as the raw material. Dr. James has obtained a series of novel chemical products which appear to have a broad field of industrial application. The process used is essentially the vapor phase, catalytic oxidation of aliphatic hydrocarbons. Among the products thus obtained are certain oxygenated acids with resin-like properties which may perhaps be utilized as cheap varnish gums and paint film substitutes, an unsaponifiable oil which can be used in lubricating greases, and finally a new fuel which might be called an "oxidized kerosene." The methods of procedure and the yields obtained are given in Prof. James' paper, which is to appear in a subsequent issue of this magazine.

USES OF LIME AND GLASS IN CHEMICAL INDUSTRY

M. E. Holmes, manager of the chemical department, National Lime Association, presented a paper entitled "An Outline of the Uses of Lime." The importance of this material to the chemist and chemical engineer is not always recognized nor is it generally known that practically 60 per cent of the total output of lime is consumed in the chemical industries. Mr. Holmes' paper and chart showing the many uses of lime for construction, agricultural and chemical purposes will be published in an early number of CHEMICAL & METALLURGICAL ENGINEERING.

A. E. Marshall, consulting engineer, of Baltimore, outlined some recent developments in the use of glass as a construction material for the chemical industries.

¹A paper describing the preparation of this catalyst and its properties is to appear in the September, 1921, number of the *Journal of the American Chemical Society*, the publication of which has been delayed by printers' strike.

The speaker stated that the idea of conveying warm glacial acetic acid through a distance of 100 ft. in 6-ft. lengths of 2½-in. glass tubes had occurred to him after observation of a somewhat similar use of glass in an English plant where hydrochloric acid was being made by the salt-cake process. He has since found that manufacturers in this country are equipped to make much larger glass pipes (up to 6 in.) and various other shapes so that there is a promising possibility of developing glass in plant construction, particularly in condensing, conveying and catalytic processes in which transparency is a real advantage. Discussion by Messrs. H. K. Moore, A. S. Cushman and others brought out many additional applications of glass in large-scale chemical processes.

REGENERATIVE EVAPORATION

Prof. W. L. Badger presented an interesting review of the subject of regenerative evaporation. A brief abstract of his remarks follows:

The idea of compressing the vapors from an evaporation to the point where they could be re-used for heating was first proposed in 1840. At that time the evaporation industries were not ready for such ideas. It was advanced again in 1872 and in 1882. The idea was then fully appreciated, but inadequate mechanical equipment prevented its adoption.

Within the last decade much attention has been given to this question, a number of machines developed, and many patents taken out. There is a voluminous literature on this subject, but most of it is from those who are directly interested in one or another of the devices offered.

That it is possible, by regenerative evaporation, to attain multiple effect efficiency in a single effect is the claim of most of these articles. This is perfectly true. However, the work necessary to compress a pound of steam from the pressure of the vapor space to that of the heating space is approximately proportional to the temperature range through which compression is effected. Hence to make the power consumption reasonable, it is necessary to choose a small working temperature drop. If the solution which is evaporated has an appreciable elevation of boiling point, the vapor must be compressed through the useful temperature range, plus this elevation. In many cases this useless work of compressing through the boiling point elevation will be greater than the useful work of compression through the working temperature range. Hence the working temperature drop must be less than 10 deg. C., and in some cases as low as 3 deg. C.

In the case of a multiple effect evaporator, only in the first effect of a triple or quadruple effect will the temperature drop be small enough to permit the operation of a regenerator. In such a case the problem is very complicated and a general answer cannot be given. Each case has to be decided in the light of its own conditions, though there will be a large fraction of all the cases in which the regenerator will not prove economical.

DEVELOPMENTS OF CHEMISTRY IN FRANCE

The last speaker to be introduced by President Wesson was Prof. Cavalier, president of the University of Toulouse and professor of metallurgy in that institution. He gave an illustrated address on the development of chemistry in France, particularly in connection with the growth and progress in methods of instruction. The universities and colleges in France now have an annual enrollment of 400 to 500 students in chemistry, and a large proportion of these are being trained as chemical engineers.

During the afternoon the visitors were given an opportunity to visit Baltimore plants engaged in chemical and allied lines of manufacture. Special automobiles were provided and parties were conducted through the plants of the Baltimore Copper Works, Standard Oil Co., Maryland Glass Co., Emerson Drug Co., McCor-

NIGHT VIEW OF BALTIMORE'S BUSINESS DISTRICT

mick & Co., National Enameling & Stamping Co., and Baltimore Tin Decorating Co.

CONVENTION BANQUET

The annual dinner at the Emerson Hotel, Friday evening, marked the formal closing of the Institute's meeting in Baltimore. The toastmaster was Albert E. Marshall and the after-dinner speakers included Major Atkinson, personal representative of Brigadier-General Fries, Dr. Charles L. Reese of Wilmington, Dr. W. B. D. Penniman and Henry F. Baker of Baltimore, Dr. C. B. Morey of Buffalo, the Institute's secretary, Dr. J. C. Olsen, the retiring president, David Wesson, and President-Elect Henry Howard. In outlining his policies on the problems confronting the Institute, Mr. Howard declared that he favored a revision of the qualifications for membership, which should not, however, in any way lower the high standards of the Institute. After definitely establishing these standards, an effort should be made to increase the Institute's membership until it included all properly qualified chemical engineers. President Howard expressed the hope that the Institute's cordial relations with other scientific and professional organizations might continue and urged the members to co-operate heartily with the American Chemical Society, but at the same time keep in mind the need for maintaining the Institute as an independent organization of American chemical engineers.

New Magnet Steel

The large amount of apparatus, particularly precision and measuring instruments, possessing permanent magnets, generally of small dimensions, necessitates the finding of a metal highly susceptible to the acquisition and retention of magnetic properties. An important steel from this point of view, called K.S., discovered by a Japanese, has the composition: Carbon, 0.4 to 0.8 per cent; cobalt, 30 to 40 per cent; chromium, 1.5 to 3 per cent; tungsten, 5 to 9 per cent. It is very brittle and very hard, and great care has to be exercised in its manufacture. Its characteristics are surprising; its coercive range is about three times that of the best tungsten steel; the area of the hysteresis curve is also three times as great; the remanent magnetism is relatively very high; lastly, shocks and prolonged heating have a negligible effect on the magnetization. In shock tests, a slight diminution in remanent magnetism was observed—6 per cent after 850 impacts by dropping from a height of 1 meter to a cement floor.—*The Ironmonger*, Oct. 22, 1921.

Some Business Aspects of the 1921 Revenue Act

BY ROBERT MURRAY HAIG*

AMONG the numerous changes made by the new tax bill signed by President Harding on Nov. 23, five stand out as of great importance from the point of view of the business man and the investor. These are:

(1) The abolition of the excess profits tax as of Jan. 1, 1922, coupled with an increase in the income tax on corporations at that time from 10 to 12½ per cent.

(2) The reduction in the surtax rates on individual incomes which comes into effect at the same time.

(3) The establishment, with the beginning of next year, of a new class of income to be known as capital gain, subject to a maximum rate of 12½ per cent.

(4) The broadening of the definition of the "closed transaction," effective for the current year, which makes possible many exchanges of property for property without subjecting the gain to taxation.

(5) The recognition, beginning this year, of a net loss from one year's operation as an offset against any profits which may accrue in the two following years.

The first two changes have been the subject of wide comment, but the other changes, being of a somewhat more technical character, have been less discussed and their significance is less fully appreciated.

NEW CLASS OF "CAPITAL GAINS"

The most revolutionary section in the new act is section 206, which sets up a new division of income. After the first of next year money made by individuals by selling or exchanging property "held for profit or investment" is subject to a maximum rate of 12½ per cent, instead of the regular rates, which range as high as 58 per cent (normal plus surtaxes). This is hedged about by several restrictions. The individual may not take advantage of the permission to use the 12½ per cent rate unless he is willing to pay at least 12½ per cent on his other income as well. The property "held for profit or investment" must have been so held for more than two years and may not include property "held for the personal use or consumption of the taxpayer or his family," or property which properly is subject to inventory. It is not necessary, however, that the property be connected with his trade or business.

The reason for the adoption of some such section as this is plain, whatever one may think of the wisdom of choosing this particular method of meeting the situation. As everyone knows, many sales of property have been postponed or entirely blocked by the unwillingness of prospective sellers to take their profits when they would immediately become subject to heavy surtaxes. This, of course, handicapped business. The solution adopted was practically to wipe out the offensive surtaxes on profits from this class of transactions.

One anomalous result of the selection of this solution, however, is that under this new arrangement a dollar of profit made from property which has grown in value is taxed at the maximum only 12½c., whereas a dollar made otherwise may be taxed as much as 50c. For example, in the case of a bond bought at a discount and sold at a profit, every dollar of interest on the bond may pay a tax nearly five times as great as every dollar

of appreciation in the value of the bond, a fact which is likely to effect profoundly future methods of corporate financing.

Much more could be said regarding the effects of this new section from the points of view of equity and of administration, but what is of particular interest here is to point out the very substantial relief granted by it to investors in property which appreciates in value.

THE "CLOSED TRANSACTION"

The advantage to the investor in property which is gaining in value, conferred by the section just described, is accentuated by the liberal provisions governing the "closed transaction." (Section 202.) This has long been a troublesome section of the field of income tax procedure. When one exchanges property for cash, no question arises. The transaction is "closed" and one accounts for his gain to the tax collector. But when one barter instead of sells, receiving other property instead of cash for his property, very serious questions arise. There are sometimes differences of opinion as to the value of the property received, which lead to disputes and litigation. The old law went so far as to say that, in the case of such trades, the property received was to be treated as cash "to the amount of its fair market value, if any" (with certain exceptions in the case of a corporate reorganization, 1918 law, section 202). The new law goes much further. It now states positively that no gain or loss on trades shall be recognized unless the property received on the trade "has a readily realizable market value." The phrase, "readily realizable," adds a new and liberalizing element.

Even more important, however, are the exceptions made to the general rule. Even though the property received has such a "readily realizable market value," one need not account for the gain in certain cases. This is one:

"When any such property held for investment or for productive use in trade or business (not including stock in trade or other property held primarily for sale) is exchanged for property of a like kind or use."

How the Treasury will interpret this section is, of course, as yet unknown, but it would be a very narrow interpretation which would exclude exchanges of bonds or real estate for real estate. In other words, so long as one "barter" or "trades" his property for other similar property instead of selling it for cash, he need not account for his gains to the Treasury for tax purposes. Even if he does sell for cash, as has been noted above, he is subject to a tax of only 12½ per cent.

NET LOSSES

With one minor exception included in the 1918 law, it has been the practice since the beginning of income taxation in this country to treat each year as a unit and to refuse to permit the fact that one has lost money this year to affect the amount of profits he must report the following year. Each accounting period has been carefully "insulated" from other accounting periods. This practice has worked much hardship and the new law breaks away from the old precedents by inserting a provision, effective for 1921 (section 204, with a restriction on mines), which permits a net loss suffered in one year to be offset against any net income in the two next succeeding years. In other words, losses may be used to blot off subsequent gains, but losses are "outlawed" for this purpose after the expiration of two years.

Destructive Distillation of Mixtures of Oil and Coal

A Comparative Study of Destructive Distillation Experiments on Coal, Oil and Mixtures of the Two in the Form of an Amalgam—Yield of Distillation Products—Composition of Tars—Nature of Light Oils—Quality of Gas—Residues

By JOSEPH D. DAVIS,* PALMER B. PLACE† AND G. S. SCOTT‡

IN THE course of investigations into the properties of mixtures of oil and coal made by the Bureau of Mines in co-operation with the Trent Process Corporation, a comparative study was made of the behavior of these mixtures and their constituents on destructive distillation. Mixtures of a petroleum oil and bituminous coal were first distilled under carefully controlled conditions, and then charges of the same oil and coal were distilled separately under similar conditions.

The quantity and quality of the distillation products were determined and results were compared. This comparison furnished a basis for judging whether greater values in products can be obtained by distillation of oil and coal in mixtures than by their separate distillation. In making the mixtures, the method use by the Trent process in cleaning coal was followed. The paste or plastic emulsion of oil and coal obtained is called "amalgam."¹

When finely pulverized wet coal is mixed with approximately one-third its weight of oil, and agitated with a large excess of water, the coal and oil agglomerate to form a paste or amalgam. A large portion of the extraneous ash originally in the coal remains suspended in the water, with which it can be decanted from the amalgam. If the latter is now thoroughly drained and kneaded after the manner of working butter, most of the excess water enclosed can be removed. This, in brief, constitutes the Trent process for cleaning coal.

The effectiveness of the process for cleaning coal has been studied² by the bureau, and the results of the study show, in general, a high ash reduction and good recovery of combustible from coals of medium and high rank. With coals of the lowest rank, such as lignites, the process is only moderately successful, owing to the difficulty attending the preparation of coherent amalgam. Oil losses to water and refuse are small, and apparently it would be practical to rotate the same oil in the cleaning process if some efficient method were devised for recovering it from the amalgam, so a distillation process naturally suggested itself.

The oil used in making amalgams may be recovered from them by distillation. If it is completely volatile below the decomposition temperature of the coal, recovery is good and neither oil nor coal is appreciably altered in the process. If, however, a heavy, high-boiling oil is used, good recovery cannot be obtained without destructive distillation, in which case the distillates will contain decomposition products of both coal and oil. Generally a rich gas is also obtained, and

the tendency is toward the production of a better coke than would be obtained from the coal alone on account of the cementing power of the oil residue. Even non-coking bituminous coals, when destructively distilled in heavy oil amalgams, will yield coke of fair quality and at least as much oil as would be obtained by refining the oil separately. The oil distilled from such amalgams is, of course, mixed with tar from the coal. In this connection it is important to know how the distillation products from heavy oil amalgams compare, both in quantity and quality, with those obtainable from the same quantities of oil and coal distilled separately. Any appreciable loss sustained through distillation of the mixed materials would tend to limit the choice of oils used in the cleaning process to those of low boiling range; any gain realized should be obtained also with oil-coal mixtures other than Trent amalgams.

The experimental work described later concerned only one class of oil and one class of coal. It was designed to show, by destructive distillation of amalgams and their constituents under exactly the same conditions:

(1) The comparative quantities of oil, residue and gas yielded by amalgams and by like quantities of oil and coal distilled separately. (2) The comparative qualities of oil and gases obtained. (3) The extent of cracking brought about by virtue of pre-mixing.

Theoretical Considerations

The theory of destructive distillation has not been developed sufficiently to enable one to predict with confidence from theoretical considerations the effect on their distillation products of pre-mixing such materials as oil and coal, the chief reason for this being a lack of knowledge of the chemistry of destructive distillation in general. It is known, however, that the chemical reactions involved are very sensitive to slight changes in distillation conditions, such as temperature, pressure and heating rate. It is important, therefore, in making comparisons, as with the problem at hand, to maintain similar conditions for all comparative experiments.

Chemically, there seems to be no interaction of oil and coal during formation of amalgams, and it is doubtful whether there is interaction in the retort before decomposition begins. During decomposition one would not expect reaction between the decomposition products of oil and coal, but, owing to the relatively large volume of vapors from the mixture, one might well expect more primary distillation products from the coal than when distilled alone, and less cracking of the oil vapors. The effect, purely physical, of large vapor volume would be to withdraw the vapors rapidly from the hot zone of the retort, thus tending to prevent secondary decomposition. The mixture of oil and coal considered here is certainly quite different physically from a simple sum of three parts oil and seven parts coal.

Amalgam is, in effect, a physical reaction product

¹The term amalgam is used here in its broadest sense—that is, to designate an intimate mixture of materials.

²Perrott, G. St. J., and Kinney, S. P., "The Use of Oil in Cleaning Coal," CHEM. & MET. ENG., vol. 25, Aug. 3, 1921, p. 182.

obtained on adding oil to wet coal in the proper proportions, and what may be called the driving force in this reaction is surface tension. Oil wets the coal by preference, and water wets the mineral matter, and both must be held at the respective surfaces with appreciable force, depending on the extent of surface affected. Theoretically, the distances through which such forces act are of molecular dimensions; that is, the nearer the thickness of the liquid film approaches to the diameter of a molecule the greater the force with which the film is held. With each succeeding layer of liquid molecules, the force of attraction diminishes.

Nelson and Hulett³ computed the amount of moisture in a film of molecular thickness spread over colloidal coal particles in 1 c.c. of the substance, and found approximately 0.06 c.c., or over 5 per cent of the weight of the coal. This water is so condensed that it has practically no vapor pressure at room temperature. The coal is sensibly dry. The same writers show experimentally that some moisture is retained by the coal at temperatures as high as 230 deg. C. Since, in a mixture of coal, oil and water, the oil wets the coal preferentially, one must assume that the force attracting the oil film to the coal is greater than that attracting the water; and one would expect films of heavy oils, particularly those of vapor pressure lower than that of water, to be held by the coal up to temperatures at which it begins to decompose.

INDICATION OF MAGNITUDE OF SURFACE FORCES

The amount of oil held at the surface of coal particles in an amalgam is difficult to estimate, and there is no direct method for measuring the surface forces involved. The writers found, however, on subjecting a navy fuel oil amalgam to pressure in a hydraulic filter press, that at pressures up to 31,000 lb. per sq.in., 5 per cent of the oil was still retained in the residue. This residue contained only a trace of water, which could be removed by drying at 105 deg. C., although the coal contained originally about 1 per cent moisture removable at that temperature.

* Oil soluble in 95 per cent H_2SO_4 , gravity 1.84, is called here "unsaturates"; "aromatics" are those oils insoluble in 95 per cent H_2SO_4 , but soluble in 37N H_2SO_4 .

It might be argued that distillation of the surface oil in an amalgam is analogous to distillation under pressure, a condition known to favor cracking reactions and the production of light liquid products. As a matter of fact, however, mixtures distilled in this research did not consistently produce more light liquid products than the constituents, but more and richer gas was obtained, and the tars contained a higher percentage of pitch. Cracking reactions were, therefore, favored by pre-mixing the materials, but the tendency was toward the formation of gaseous products rather than condensable liquids, as in the case of oil cracking under pressure. Actually, considerably more oil is required to make a coherent amalgam than can be accounted for in a film a few molecules thick enclosing

FIG. 1. COAL DISTILLATION APPARATUS

the coal, even if the individual coal particles are of colloidal size. Apparently, the distillation of this excess oil is not affected by the presence of the coal, and the total cracking effect observed in the distillation of the mixtures was due to the forces in the thin film.

The distillation of amalgams or mixtures containing large quantities of enclosed water results in the steam distillation of some of the heavy oils at temperatures below their normal boiling points. It is not believed, however, that steam has any appreciable effect on that portion of the oil in the molecular film enclosing the coal, since the vapor pressure of this oil must be very low. Further, parallel distillation tests made, wherein for one test the mixtures were made up dry, and for the other they were worked and air-dried to remove excess water, yielded approximately the same products. In other words, amalgams from which all excess water has been removed behave in the same way as dry mixtures on distillation.

Experimental Data

In order that the tests made at different temperatures in the distillation series of this paper be comparable, the same materials were used in all cases. The coal used was bituminous, and was obtained from the Big Muddy Coal & Iron Co., Herrin, Ill. The oil, a topped crude of asphaltic base, designated as navy fuel oil, was supplied by the Trent Process Corporation. Its specific gravity was 0.875 at 20 deg. C., and the viscosity 125 seconds Saybolt at 25 deg. C. The proximate analysis of the coal is given in Table I, together with fractionation results for the oil and an analysis of the oil fractions.

A sketch of the apparatus used is shown in Fig. 1. The retort *a* was made from a 48-in. length of heavy 6-in. iron pipe, which was insulated with asbestos paper and wound with nichrome wire for electric heating. The sheet metal casing *e* held a packing of infusorial earth for heat insulation. The top of the retort was provided with a hopper and worm *f* for uniform feeding of amalgam and coal; a 500-c.c. separatory funnel

served for feeding the oil. The distillation vapors and gases from the retort passed out through the pipe *j*, over the tar trap *k*, and into the water-cooled condensers *l* and *l'*, where most of the water and tar were condensed. A Cottrell precipitator *m* served to remove tar mists remaining in the gas, and the U-tube *n*, which was filled with gas-mask charcoal, retained light oils carried by the gas. A rotary pump *o* with an adjustable bypass *p* was used to keep a uniform pressure on the retort, and gas volumes were measured by the dry meter *q*.

TEST PROCEDURE

The distillation conditions for these tests approached those prevailing in the cracking of gas oil for the carburation of water gas. The object was a complete and rapid breaking up of the materials, as it was believed that by this treatment the cracking of oils and tars would be thorough; differences in cracking tendency of the materials would be exaggerated, and therefore easy to detect by analyzing the products. The method consisted in feeding the charges in small increments into the retort, previously heated to the temperature decided upon, this temperature being maintained as nearly constant as possible during the experiment.

Five series of tests were made, one at each of the temperatures 400, 500, 600, 700 and 800 deg. C. Each series included three distillations—one of the amalgam, one of the oil and one of the coal.

Amalgams were distilled first, and in each case a uniform rate of feed was maintained, which gave a fairly constant rate of gas evolution. This was noted, and in subsequent distillations of oil and coal separately at the same temperature the feed was adjusted to give a similar rate of gas evolution. Thus the gases and vapors from amalgam, coal and oil, respectively, remained in the retort for the same period. No fixed weight of charge was predetermined. The runs were continued until it was judged that a sufficient quantity of distillation products had been collected for chemical examination. All parts of the condensing train were weighed before and after each run, and the adhering tars were removed as thoroughly as possible and mixed for analysis. Light oils caught in the charcoal absorber were analyzed separately.

On account of their complexity, analysis of the tars presented considerable difficulty. Methods for the analysis of petroleum were not strictly applicable, nor were those used in the analysis of coal tar. After con-

siderable experimentation, the methods described by Weiss⁴ for the analysis of coal tar were adopted, with slight modification. Briefly, the procedure was as follows:

A sample of 300 c.c. of the tar was dehydrated in a standard Barrett copper retort, fitted with a copper condensing trough, according to the method of Weiss, by heating continuously to 170 deg. C. The water distilling was collected in a 100-c.c. graduate, where its volume could be read directly. Any light oil distilling with the water was returned to the retort, after which the tar, now dry, was fractionated. Cuts were taken every 25 deg. All fractions boiling under 200 deg. C. were united, as were also those boiling between 200 and 350 deg. C., and the united fractions were analyzed for tar acids, tar bases, unsaturated compounds and paraffines.

The analysis was carried out in standard Barrett graduated separatory funnels, and consisted in washing the distillates successively with 10 per cent caustic soda for acids, 20 per cent H_2SO_4 for bases, 95 per cent H_2SO_4 (1.84 sp.gr.) for unsaturates, and 37N H_2SO_4 for aromatics. The contraction in the oil volume observed after repeated washings with the reagents represented the amount of the several constituents present. The residue unattacked by reagents represented paraffines. In this connection it must be observed that the washing test with 95 per cent H_2SO_4 , although it was formerly depended on in the petroleum industry, has recently⁵ been shown to give results of only approximate accuracy. This is particularly true with mixtures containing the higher olefines. However, since some idea of the amount of unsaturated compounds present in the distillates was highly desirable, and since this method was the only one available, it was used as giving approximate results and of value for comparison.

As would be expected from such a series of distillation tests on a small scale, the experimental error was rather large and an absolute interpretation cannot, therefore, be placed on the figures obtained. Their chief significance lies in their value for purposes of comparison, and the following general conclusions may be drawn:

(1) The amalgams at all temperatures yield less resi-

* Results for residue and tar uncertain, fixed carbon carried over from retort into tar trap.

due than would be obtained by distillation of their constituents separately.

(2) The amalgams yield a greater quantity of tar than their constituents except at 500 deg. C., where conditions favor the complete distillation of the oil without excessive cracking into gas.

(3) The amalgams yield a larger volume of gas than

FIG. 2. RESIDUE VARIATION WITH TEMPERATURE

the constituents as a rule, and incidentally it has uniformly a higher heating value than that from constituents (see Table IV), but its specific gravity is lower.

(4) The total light oil yield is usually greater for the amalgams. The difference in yield, however, is small, perhaps within the limit of experimental error.

(5) At 800 deg. all tars are almost completely cracked into gases and fixed carbon.

Table II gives the yield figures for all distillation tests of amalgam, coal, oil, and the sum. This last item was calculated from the separate distillations of coal and oil, and represents what would be obtained by distilling 30 parts of oil and 70 parts of coal separately, and combining the products. The graphs in Figs. 2, 3, 4 and 5 show the variation in yield of the products,

FIG. 3. TAR YIELD VARIATION WITH TEMPERATURE

residue, total oil, light oils and gas respectively, with temperature.

In the case of batch distillations of amalgam included in Table II for temperatures 600 and 800 deg. C., the total charge was placed in the cold retort and heated gradually to distillation temperature. At both temperatures there was a much larger yield of gas by the continuous method, the high yield apparently being at the expense of the residue at 600 deg. C., and at the expense of the tar at 800 deg. C.

Comparing the behavior of the amalgam with that of its constituents on distillation, as shown by the quality of the tars (Fig. 6), it is clear that it is the more sensitive to temperature. At 400 deg. C. the distillation residue is practically the same as that calculated for the sum of its constituents, but with higher distillation temperatures it becomes much greater than that for the sum. A higher percentage of pitch carbon in the amalgam tars is indicated, and hence a more extensive cracking with rising temperature. Corre-

sponding to this, one might expect an increase of unsaturates and aromatics in the amalgam tars, but as a matter of fact these tars contain less aromatics and unsaturates at the higher temperatures than that calculated for them. The products of the cracking must therefore be found in the gas, and, as previously shown, this is borne out by a higher yield of richer gas for the amalgams.

As would be expected, the paraffine content of the tars drops rapidly with rising temperature for all continuous distillations to practically zero at 70 deg. The paraffine content of the amalgam tars is lower than the calculated values for all distillation temperatures except 400 deg. C. This is further evidence of the more complete thermal decomposition of amalgam tars.

In general, the oils known to be largely composed of paraffines originally react in the same way as the coal under the influence of heat. The constituents of

FIG. 4. TOTAL OILS BOILING UNDER 200 DEG. C.

the tars vary similarly with rising temperature. Neglecting compounds that produce phenols, it can be argued that the volatile constituents of coal are largely of a paraffine nature.⁶

Table III gives the composition of the tars, and Figs. 6, 7, 8 and 9 show the variation in tar quality with temperature.

Tars from batch distillations at 600 and 800 deg. C., wherever the whole amalgam charge was placed in the cold retort and heated gradually to the distillation temperature, show much less thermal decomposition than tars obtained by the continuous method. The paraffine content even at 800 deg. was 41 and 65.8 per cent; whereas the tars from the continuous method were so broken up that analysis was impractical. Actually, most of the tar from the batch distillation came off at much lower temperatures than 800 deg. C.—that is, during

* Boiling 200-300 deg. C.

† Tar consisted of heavy hydrocarbons and fixed carbon, regular analysis impractical.

the gradual heating to that temperature. By feeding the charge continuously in small increments, it was all heated almost instantaneously to the highest distillation temperature, and distillation took place, to borrow an expression from steam boiler technology, "from and at" that temperature.

Light oils absorbed by passing the gas through gas-mask charcoal consisted almost entirely of unsaturates

content. Its illuminant content was high, which fact partly accounts for its high heating value. Further, it contained more methane and less carbon monoxide than the calculated gas. Table IV gives average analyses of gases from all test runs of the series, together with an analysis of amalgam gas for each temperature calculated from the gas yields of oil and coal.

The total heating value of the amalgam gas is superior to that obtained from its constituents distilled alone, as the following approximate calculation shows:

FIG. 6. TAR DISTILLATION RESIDUES

and aromatics, except where amalgams were distilled in batch and where the coal was distilled at 400 deg. C. Appreciable quantities of paraffines were here present. Eighty to 90 per cent of the oils extracted by the continuous distillation method were volatile under 100 deg. C., and practically all of them were completely volatile under 125 deg. C. The light oil from the coal distillation at 400 deg. C. was not completely distilled until a temperature of 200 deg. C. was reached, and then a tarry residue amounting to 5 per cent of the oil remained. The presence of condensable compounds, such as indene and cumarone, is thus indicated.

Several samples of gas were taken at corresponding time intervals during each distillation test, and the analyses of these grab samples were averaged. All samples were taken after the gas had passed the light oil scrubber, and their heating value was therefore lower than that of the raw gas.

For the most part, the gas yielded by the amalgams was better than that calculated for them from the gases obtained from the oil and coal; its volume also was greater. The weight per cent yield of amalgam gas was low (see Table II) chiefly owing to a low CO,

	Distillation Temp., Deg. C.	B.t.u. per Cu.Ft.	Cu.Ft. per Ton	B.t.u. in Gas From 1-Ton Charge

in the carburization of water gas, if a method were devised for handling the residues produced.

In no case where the continuous distillation method was employed was the residue coked. It was in the form of a fine powder, there being little tendency to

FIG. 8. TOTAL AROMATICS IN TAR

fusion, and contained at the higher temperatures a considerable quantity of finely divided carbon, a product of tar cracking reactions. Batch distillations of amalgams yielded a fairly coherent coke, but apparently no better than that from the coal alone.

CONCLUSIONS

Oil and coal were distilled under carefully controlled conditions at the temperatures 400, 500, 600, 700 and 800 deg. C., and amalgams of oil and coal were then distilled under similar conditions, and the distillation products were compared. For this purpose, the yields to be expected for the amalgams were calculated at each temperature from the yields obtained from the oil and coal distilled alone.

The distillation method used was unique in that it aimed at a rapid and complete destructive distillation of the materials within a narrow temperature range. The effect of this method was to bring about a more rapid thermal decomposition, and at lower apparent temperatures than is the rule in destructive distillation practice. The conditions of distillation were very similar to those prevailing in the carburization of water gas.

Comparison of the products shows in general that different results are obtained by distilling amalgams or mixtures of oil and coal from those obtained by distilling the constituents separately. Consistent differ-

ences appear in the quantity of residues obtained, and in the quantity and quality of the gases. Differences in the tar products are not so well defined. Light oils extracted vary in quantity and quality, but probably within the limits of experimental error. The results show that for this distillation method:

(1) Amalgams are more sensitive to temperature than their constituents. This is probably due to the fact that in the amalgams a part of the oil is held by surface tension forces in contact with the coal at temperatures above its boiling point.

(2) Amalgams yield a smaller distillation residue than their constituents, and a larger volume of gas.

FIG. 9. TOTAL PARAFFINE CONTENT IN TAR

Further, the quality of this gas is better than the combined gases from coal and oil.

(3) Amalgams do not give a better light oil yield than their constituents, but they give a higher yield of tar, which is of poorer quality, containing excessive quantities of pitch.

Boiling Point of Salt Solutions Under Varying Pressures*

Derivation of a General Law Which Greatly Simplifies the Accurate Determination of Important Data on the Boiling Points, Over the Usual Range of Pressure and Concentration, of Salt Solutions Commonly Evaporated in Vacuum Evaporators

BY E. M. BAKER AND V. H. WAITE

IN AN EARLIER paper¹ attention was called to the fact that in the design of an evaporator installation it is necessary to know the elevation of the boiling point of the solution being evaporated in each effect, at the temperature and pressure existing in that effect. It was further pointed out that while the literature shows a large number of determinations of the elevation of boiling points of aqueous solutions, many of these determinations were made at comparatively early dates with crude apparatus, and hence there frequently were wide variations in the values reported. This laboratory announced the intention of proceeding with the determination of the vapor pressure curves of such solutions as are used by the chemical industry and are commonly concentrated in vacuum evaporators. The Division of Chemistry and Chemical Technology of the National Research Council became interested in this work and made it one of its supported projects. The Council desired that the work be carried out to a greater degree of accuracy than was determined for technical purposes, in order that the data obtained might have a higher value for use in purely theoretical studies. To meet this condition, it was necessary to develop an apparatus in which the pressure could be maintained practically constant and in which other sources of error might be kept below a fixed maximum. The limit considered permissible for this work was placed at an absolute error of 0.1 deg. C.

DESCRIPTION OF APPARATUS

A sketch, partly diagrammatic, of the apparatus used is shown in Fig. 1. The solution whose vapor pressure was to be determined at different temperatures was placed in the glass tube *I* and then heated by an electric current passing through resistance coils in the heater *C*. The current was regulated by an external resistance and the current and voltage used were read on suitable meters. A modified Cottrell² pumping tube *D* was slipped down over the heater and used for pumping a mixture of the solution and vapor over the platinum resistance thermometer *B*. The tube *I* was jacketed with a second glass tube, *E*, to minimize the effect of air currents. The vapors coming from the boiling solution passed into a condenser *G*, to which is connected a large glass reservoir *H*. From *H* a line of glass tubing leads to a small catch bottle *J*, connected to a laboratory water-jet vacuum pump. This catch bottle was also connected to a vacuum regulator, consisting of two parts, a manometer *M* and a needle valve operated by the solenoid *K*. An increase in the vacuum over the

value desired would cause the mercury to rise in the manometer and in turn make a contact with the platinum tipped rod *F*, and complete a low-voltage circuit through the mercury and the relay *R*. This caused the relay to complete a 220-volt direct-current circuit through the solenoid *K*, thus pulling up its armature. The lower end of this armature constituted the plug of the needle valve.

It is necessary to be able to regulate the lift of the needle valve since different openings are required for

FIG. 1. SKETCH OF APPARATUS

best regulation at different absolute pressures. This regulation is obtained by screwing the upper end of the solenoid core up or down to the required position. By a proper setting of the pump the vacuum is regulated to a value slightly in excess of that wanted, and the "vacuum regulator" used to give the vacuum desired. The mercury in the regulating manometer oscil-

lates regularly up and down, the magnitude of the oscillations being about 3 mm. The reservoir or vessel of large capacity *H* served to damp these oscillations, and to maintain the vacuum in the boiling point apparatus at a very constant value. This vacuum was measured by a manometer *A* connected directly into the boiling-point tube, thus insuring that the pressure read was the true pressure under which the liquid was boiling. The manometer was made of 10-mm. glass tubing in order to minimize the effect of capillary action. The variations in pressure in the boiling-point tube were so slight that the bottom of the mercury meniscus in the measuring manometer would show no perceptible movement over periods as long as a half hour, but the center of the meniscus would breathe or oscillate regularly up and down a distance of 0.1 to 0.3 mm. This measuring manometer was mounted against a mirror to aid in eliminating the parallax in reading. The value of the manometer reading was taken by a steel rule graduated in half millimeters and mounted so that it could be racked up and down over the manometer. In making a pressure reading, the rule was adjusted so that its bottom edge was just level with the center of the mercury meniscus in the low arm, and the graduated edge of the rule came to the center line of the mercury in the high arm. The reading of the center of the meniscus in the high arm was taken with the aid of a magnifying glass, care being used to avoid errors of parallax.

METHODS OF MEASURING TEMPERATURE AND PRESSURE

A 10-mm. tube filled with mercury was hung beside the measuring manometer, and its temperature read on a mercury thermometer whose bulb extended some distance down in this mercury. The temperature so read was taken as the temperature of the mercury in the measuring manometer. By this means the effect of lag with changing room temperatures was eliminated.

The temperature of the boiling solution was taken by a platinum resistance thermometer *B*. Except where otherwise noted, this thermometer was not immersed in the body of the liquid, but was in the vapor space. The thermometer tube was kept well wetted with solution for a distance about an inch above the platinum coil by means of the pumping tube *D*. The resistance thermometer was constructed according to the method as given by the Bureau of Standards,³ and was provided with compensating leads. The resistance was measured by means of a bridge with a wall galvanometer. In calibrating the thermometer and at all other times, the resistances corresponding to *A* and *B* in the formula

$$X = \frac{A}{B} R$$

were each 1,000 ohms, and the same re-

sistance coils were used for *A* and *B* throughout. For adjusting the resistance *R* to balance *X* a precision resistance was placed in parallel with the resistance *R* of the bridge proper. The precision resistance was adjusted to a value slightly greater than *X* and the final adjustment obtained by adjusting the resistance of the bridge. This latter resistance would always be large, at least 500 ohms, so that the accuracy of the bridge as a whole was determined by the galvanometer and the precision resistance. One of the three leads to the thermometer was connected in the battery circuit, and the two other leads were placed one in each of the arms *X* and *R*. These latter two leads were at no time

interchanged from the position they occupied at the time of calibration. A compensated aneroid barometer was used for measuring the barometric pressure. This barometer was compared at different times with the mercury barometer of the university observatory, and a calibration curve constructed.

DISCUSSION OF SOURCES OF ERROR

The general sources of error that may be experienced in boiling-point determinations have been so well discussed by Smith and Menzies⁴ and others that only those relating to this particular apparatus will be treated here.

Pressure and Temperature Control.—The vacuum regulator made it possible to maintain a constant mean difference between the barometric pressure and the pressure in the apparatus for as long a period as was desired. In some determinations the pressure in the apparatus actually oscillated as much as 0.3 mm. from the mean value, but as these oscillations were rapid and extremely regular, it may be safely assumed that their effect on the mean boiling point of the solution was nil. The temperature for all but the most concentrated and viscous solutions would be correspondingly equally constant. For the latter variations as much as 0.3 deg. C. were noted. In these cases the highest values obtained at a given pressure were taken as correct.

Temperature.—The platinum thermometer was calibrated against the temperature of melting ice, of steam above boiling water, and of the vapor above boiling naphthalene. From the resistance obtained at these three points the constants in the formula $R_t = R_0 (1 + \alpha t + \beta t^2)$ were determined. A calibration curve was then constructed using a scale such that 1 mm. corresponded to 0.1 deg. C. The values for temperature as read are calculated to be accurate to within less than 0.1 deg. C.

Pressure.—The pressures as measured by the mercury barometer and manometer were reduced to equivalent readings at 0 deg. C., 45 deg. latitude and sea level, and the values reported have all been so corrected. The steel rule used was compared with other standards and found to check to within less than 0.1 mm. at 25 deg. C. The height of the mercury column could be read as accurately as a mercury barometer. In taking these readings, the difference in height of the top of the meniscus in the two arms of the manometer was taken as the reading. It can be easily demonstrated that if the mercury column is oscillating regularly, the above reading is the true mean value. The mercury used had been purified by nitric acid, followed by a double distillation in vacuo.

Purity of Materials.—The materials used were sufficiently purified so that errors from this source could not cause an error of 0.1 deg. C. in the boiling point of any solution used. Dissolved gases, if any were present, would be completely swept out by the ebullistic method used, since about 20 minutes was allowed at each point for the system to come to equilibrium.

Superheat.—Superheating of the liquid was practically impossible, first, because the heat was conducted to the solution through metal, and second, because the solution that came in contact with the thermometer had been pumped by its own steam up the pumping tube onto the thermometer, thus giving time for the vapor and liquid to come into equilibrium with each other.

³Scientific Paper 107.

⁴"Studies in Vapor Pressure," *J. Am. Chem. Soc.*, vol. 32, p. 1412.

This also eliminated any possibility of the boiling point of the solution in which the thermometer was immersed being raised by the hydrostatic pressure of the liquid.

ACCURACY OF COMPLETE APPARATUS

To test the general accuracy of the complete apparatus determinations of the boiling point of water from 50 to 100 deg. C. were made, using the pumping tube exactly as in the case of a solution so that the thermometer was wet with the water pumped up. These results are presented in Table I. The fifth column of this table shows the corresponding values given by Peabody's Steam Tables,⁵ which are based on accepted standard values of Holborn and Henning.⁶ From these results, it would appear that the apparatus has an

TABLE I. COMPARISON OF BOILING POINT OF WATER AT DIFFERENT PRESSURES WITH VALUES OBTAINED BY HOLBORN AND HENNING

741.0	78.4	662.6	96.20	96.20	0.00

absolute accuracy within this range of better than 0.1 deg. C. The accuracy of pressure measurement is believed to be well within 0.3 mm. It is evident that if the mercurial barometer against which the aneroid barometer was calibrated were in error by 0.3 mm., this would have made the measurement of the boiling point of water, at 123.6 mm. pressure, in error by 0.05 deg. C.

CRITICAL STUDY OF DATA

The method of making a critical study of boiling point data described in a previous paper,⁷ while satisfactory for most technical work, is not sufficiently exact to preserve the accuracy of data which have a probable absolute error of less than 0.1 deg. C. Data of this sort could be obtained by the use of a series of empirical formulas, such as those of Bertrand, but the labor involved in such a method would be enormous. In searching for a simple yet accurate method for studying the data, it was found that if at a pressure p_1 the solution boiled at a temperature t_1 , and water boiled at a temperature θ_1 , and that at a pressure p_2 the corresponding boiling points were t_2 and θ_2 , then for p_n , t_n and θ_n , the following relationship would hold:

$$\frac{t_1 - t_2}{\theta_1 - \theta_2} = \frac{t_2 - t_3}{\theta_2 - \theta_3} = \frac{t_n - t_{n+1}}{\theta_n - \theta_{n+1}} = K,$$

where K is a constant. In other words, if a series of points were plotted on rectangular co-ordinate paper, showing for a given solution the temperatures at which the solution exerted certain vapor pressures plotted against the corresponding temperatures at which water would exert the same vapor pressure, then all the points so plotted would fall more nearly on a straight line than on any other smooth curve that could be drawn. This is essentially Dühring's rule. In 1878 Dühring⁸ advanced the theory that if t_1 and t_2 are the boiling points

of a substance at two pressures, p_1 and p_2 , and if θ_1 and θ_2 are the boiling points of another substance at the same pressures, then $(t_1 - t_2) = q (\theta_1 - \theta_2)$ where q is a constant. Curiously enough, while this rule has been largely used for comparing the boiling points of different pure substances with the boiling points of water, it has apparently not been applied to aqueous solutions where the solute exerted practically no vapor pressure. The same statement holds true for the more general law of Ramsay and Young.⁹

The accuracy with which Dühring's rule can be applied to aqueous solutions of any strength, provided always that these solutions are not saturated and provided that the solute does not exert an appreciable vapor pressure, has not been generally appreciated. The ap-

FIG. 2. BOILING POINTS OF CERTAIN SOLUTIONS PLOTTED AGAINST CORRESPONDING BOILING POINTS OF WATER UNDER THE SAME PRESSURE

plication of this rule to several solutions is shown by the curves in Fig. 2. This graph shows as ordinates the boiling points of certain solutions at various pressures, and as abscissas the corresponding boiling points of water under the same pressures. The boiling point data for this graph were selected rather at random both from the literature and from determinations by the authors. Some of the solutions represented ionize highly, others

⁹Z. phys. Chem., vol. 1, p. 250.

to a less extent. Some of the solutes are not ordinarily considered to form a series of hydrated particles in solution, others are known to associate strongly. There is a great diversity of the chemical nature of the solutes considered. The actual data plotted are shown in each case by the circles. The curves as drawn are straight lines, and coincide with the data very closely. With few exceptions, the deviation is less than 0.1 deg. C., and in all cases the straight line more nearly represents the data than any other smooth curve that might be drawn. The variation of individual points from the straight line is presumably due to experimental error, and the general agreement of the data with Dühring's rule is most remarkable. That is to say, all these solutions obey

$$\text{the relationship } K = \frac{t_1 - t_2}{\theta_1 - \theta_2}$$

Accordingly, if Dühring's rule holds, as this study indicates, in order to define completely and accurately the relationship of vapor pressure to the boiling point of an unsaturated solution of any strength (an infinite number of data), it is only necessary to record two relationships—viz., a curve or table showing the boiling point of solutions of different concentrations at one pressure, for example, atmospheric pressure; and the curve or equation which shows the relation between concentration of solutions and slope of the lines for these varying concentrations.

From these two sets of data, the boiling point of a solution of any composition at any pressure may be at once calculated.

APPLICATION OF DÜHRING'S RULE

It is evident that in order to obtain the above information, instead of carrying out an indefinite number of determinations of boiling points of solutions at different strengths and pressures, it is only necessary to determine the boiling points of each of a number of solutions of different concentrations at two pressures. One of these pressures will usually be atmospheric. Thus, the establishing of the relation expressed by Dühring's rule has greatly decreased the number of determinations necessary to obtain the information and has simplified the method of recording these data.

To define completely the whole system for saturated and unsaturated solutions, it is necessary to know, in addition to the above, the boiling point of the saturated solution at different pressures, or else the solubility of the solute at different temperatures. With either of these sets of data, a line can be drawn on the chart for the system which will show, at the various solution temperatures, the solubility of the solute. The area to one side of this line will then represent unsaturated solutions for which Dühring's rule will hold; the area to the other side will represent supersaturated solutions and these should not exist under the given conditions; and the line itself will define the boiling points of the saturated solution at different pressures.

We desire to emphasize again that the relationships expressed by Dühring's rule appear to hold, for unsaturated aqueous solutions where the solute does not exert an appreciable vapor pressure, more accurately than data which have been determined, without regard to (1) whether the concentration is high or low, (2) whether or not the solute ionizes, and (3) whether or not the molecules or ions of the solute take up water of hydration or association. It is not at all necessary that the solution be "ideal," to conform rigorously to the law.

It should be pointed out that the curves in Fig. 2 are not parallel (in general) either to each other or to the curve for water, nor is there a definite relation between the slope of the curves and the elevation of the boiling point at any given pressure.

It is planned to use the apparatus and the method as described in this paper in a number of investigations. Two such investigations have already been completed, and are to be published in subsequent papers.¹⁰

The authors desire to acknowledge the assistance received from the National Research Council, which made possible this work, and of the active interest taken by Prof. W. L. Badger of this department.

Increased Production of Rosin and Turpentine

The production of rosin rose 29 per cent, or 350,000 round barrels, and that of turpentine 33 per cent, or 122,000 casks, during the season 1920-21 over that of the previous season, according to a recent statement of the United States Bureau of Chemistry.

The following table, compiled from reports from individual producers, shows the production of rosin by states for the last three years:

ROSIN PRODUCTION IN ROUND BARRELS

State	1918-19	1919-20	1920-21
Alabama	136,180	141,410	150,310
Florida	414,150	495,660	548,880
Georgia	215,550	262,050	425,530
Louisiana	165,300	130,430	214,580
Mississippi	109,120	119,610	175,810
N. Carolina	2,920	4,090	1,740
S. Carolina	2,340	3,430	8,250
Texas	68,600	64,090	52,290
Total	1,114,160	1,220,770	1,577,390

The production of turpentine by states is given below:

TURPENTINE PRODUCTION IN CASKS

State	1918-19	1919-20	1920-21
Alabama	41,580	43,800	47,220
Florida	125,680	144,180	170,870
Georgia	65,470	82,420	133,070
Louisiana	52,850	38,950	65,520
Mississippi	31,920	36,080	53,430
N. Carolina	880	1,340	530
S. Carolina	690	1,110	2,540
Texas	21,200	18,690	15,410
Total	340,270	366,570	488,590

On the Heat-Treatment of Aluminum Bronze

In the article "On the Heat-Treatment of Aluminum Bronze," by A. A. Blue, in the Dec. 7 issue of CHEMICAL & METALLURGICAL ENGINEERING, an error due to a misunderstanding occurred in Table V on page 1048. The table as corrected should read as follows:

TABLE V. PROPERTIES OF FORGED ALUMINUM BRONZE

Treatment	Tensile Strength, Lb. per Sq. In.	Elastic Limit, Lb. per Sq. In.	Elongation, per Cent	Contraction in Area, per Cent
Forged, untreated	79,750	34,360	32.5	34.8
Forged, untreated	81,245	34,240	31.0	30.8
Forged, reheated to 1,650 deg. F. and quenched in brine	92,190	44,820	Broke outside gage marks.	
Forged, reheated to 1,650 deg. F., quenched in brine, drawn to 1,000 deg. F. and cooled in lime	81,345	43,820	Broke outside gage marks.	
Forged, reheated to 1,650 deg. F., quenched in brine, drawn to 1,000 deg. F. and cooled in lime	86,490	47,760	12.0	14.9

Fatigue of Metals Under Repeated Stress

Professors Moore and Kommers Believe That Carbon Steels Will Not Fail by "Fatigue" if Stressed Below a Definite Amount, Quickly Determined by Measuring the Heat Generated in the Specimen During the Test

AS HAS been noted in these columns, Professors Moore and Kommers, of the University of Illinois, have been conducting an investigation upon fatigue failure under the joint auspices of the University Engineering Experiment Station, the Engineering Foundation and the General Electric Co. Bulletin 124 of the Experiment Station describes in considerable detail the results so far obtained.

Table I gives the chemical analysis of the steels tested; each of these was heat-treated to bring it in that condition often found in machine parts. (See Table II.) Usual physical tests were performed with the results listed in Table III. Fatigue tests were made on a battery of machines designed along lines proposed by F. M. Farmer.¹ Specimen A is rotated in swivel end bearings, and carries the load W at two places, C and D . These arrangements are designed to throw a uniform bending moment in a cylindrical specimen, but in order to localize the failure, the test-piece was reduced to a neck 0.30 in. in diameter by a fillet of 9.85 in. radius. Final polishing was done with No. 00 emery cloth.

In making the rotating-beam test on the first specimen a stress was applied which would cause failure in a short time. In successive specimens the stress was reduced until a stress was reached which the specimen could withstand for 100,000,000 cycles without failure.

FIG. 1. SKETCH OF ROTATING BEAM MACHINE FOR MEASURING ENDURANCE OF METAL

Wherever possible these long-time tests without failure were run on from three to five specimens for each of the steels investigated. Altogether 963 reversed-stress tests were made.

Fig. 2 shows the results of fatigue tests on eutectoid steel No. 6. All the diagrams are plotted with logarithmic co-ordinates, stresses against number of cycles for rupture ($S-N$ diagrams). The authors have interpreted all their plots to indicate that up to some value of N the results of the reversed-stress tests may be well represented by a sloping straight line, where there is a decided break. For higher values of N a

horizontal straight line seems to represent the relation between S and N , up to a value of N of 100,000,000 cycles of stress, with no indication of a further break in the diagram. So far as they can see from their test results, the material would withstand an indefinite number of reversals of stress lower than the value corresponding to this break in the $S-N$ diagram. To this safe stress the name "endurance limit" has been given,

FIG. 2. TEST RESULTS ON ALTERNATIONS TO FAILURE OF EUTECTOID STEEL, VARIOUSLY HEAT-TREATED

and in all the steels tested it was developed at less than 10,000,000 reversals. In other words, a steel which will not break before 10,000,000 reversals can be expected to endure 100,000,000, and perhaps forever.

Searching for some short-time test for predicting fatigue resistance, this was found by measuring the rise of temperature² under a reversed stress applied for a few minutes or less.

The apparatus used in making the temperature test is shown in Fig. 3. The machine was designed to test the regular 13-in. rotating-beam specimen and to produce the same type of stress. Specimen S is held horizontally in V-notch grips A . The load is applied on a ball bearing B , at the end of the specimen, the bearing being heat-insulated from the specimen by a fiber collar $\frac{1}{8}$ in. thick. The machine is also heat-insulated from the base at points E and F , to prevent heat traveling from the bearings through the base to the specimen. The load on the specimen is measured by reading the deflection of the Ames dial C , a load-deflection curve

²The temperature test was suggested and to some extent used by C. E. Stromeyer of Manchester, England, as long ago as 1913. He did not, however, have the opportunity of carrying out a sufficient number of long-time tests to establish thoroughly the temperature limit as identical with the endurance limit under repeated stress. It should be stated that the credit of developing the temperature test in connection with the present investigation should be given to J. W. Harsch, a member of the test party of the present investigation, and to Prof. W. J. Putnam of the department of theoretical and applied mechanics of the University of Illinois.

¹American Society for Testing Materials, 1919.

for the specimen having been previously obtained by recording a set of loads and corresponding deflection readings. The load can be varied by an adjusting screw, *D*, in the head of the machine. A thermocouple cannot be readily attached to a rotating specimen, and it will be noted that the machine is so designed that the specimen does not turn, but that the head of the machine rotates. The left-hand end of the specimen is thus moved in a circle concentric with its axis, the radius of the circle being the deflection corresponding to the desired stress.

Differential copper-constantan thermocouples were used to measure the rise of temperature. One couple was attached at the section of greatest stress *K*, and was held directly against the specimen by means of tape. The other couple was at *L*, a section of zero stress, and was separated from the specimen by a

single layer of thin paper. The couples were connected in series, and the free wires lead to a D'Arsonval galvanometer. When the couples were at the same temperature no deflection of the galvanometer was shown, but when the temperature became different a corresponding deflection occurred.

The temperature test consists in running the machine at a speed of 1,000 r.p.m. for 30 seconds, using a known stress and recording the maximum deflection of the galvanometer. Then with a series of such readings, corresponding to a series of stresses, a curve like those of Fig. 4 is plotted to show the increase in temperature with increase of stress. The point at which the curve shows a sharp break corresponds to the endurance limit. In the cases of sorbitic structures in plain carbon steels and in that of alloy steels it was found necessary to increase the time of the run, at

FIG. 3. BENDING MACHINE FOR MEASURING HEAT DEVELOPED DURING ALTERNATE STRESSING

each stress, from 30 seconds to 2 minutes, since these materials are slower in heating under stress.

A reference to Table IV and Fig. 5 shows a very good degree of coincidence between the values of endurance limit determined by the temperature test and those values determined by long-time rotating-beam tests.

Various physical properties of the steels used in this investigation are plotted in Figs. 5 and 6. It is apparent that the endurance limit (by rotating beam and logarithmic plot) corresponds most closely to the rise in temperature determinations. Fairly good parallelism exists between the curve for endurance limit and curves for Brinell hardness and ultimate tensile strength. Other properties vary widely. In none of the steels did the endurance limit under completely reversed stress fall below 36 per cent of the ultimate tensile strength; in only one metal did the endurance limit fall below 40 per cent of the ultimate tensile strength, while for several metals the endurance limit was more than 50 per cent of the ultimate tensile strength. In this connection it should be noted that the steels tested were to a high degree free from inclusions and other internal defects, that the specimens had no abrupt changes of outline, and that they had a good surface finish.

Effect of Shape of Specimens on Endurance Limit.—Previous investigators have shown that the shape of the specimen may exert a very great influence on the endurance strength of the material. Square shoulders and sharp notches are known to reduce the endurance limit as much as 50 per cent.

A study of this matter was first made in this investigation on a 0.49 carbon, sorbitic steel. It was found that specimens which had their diameter reduced by a fillet 1-in. radius were almost as strong as those in which a radius of 9.85 in. was used. A ½-in. radius reduced the strength about 8 per cent, square shoulders reduced the strength about 51 per cent, and a V-notch reduced the strength about 60 per cent. Square shoulders and a 1-in. radius showed about the same effect on a very soft 0.02 carbon as they did with the harder steel first mentioned.

Effect of Surface Finish on the Endurance Limit.—It has been known that the condition of the surface of a specimen may exert a marked influence on the fatigue strength of steel. A study of this matter was first

FIG. 4. TEST RESULTS ON MACHINE ILLUSTRATED IN FIG. 3

made on a 0.49 carbon, sorbitic steel. One series of specimens was finished very carefully in order to remove all scratches and was finally given a very high rouge polish. It was found that these specimens were only slightly stronger than those finished with the standard finish. Specimens with a ground finish were slightly weaker than those with the rouge finish, smooth-turned still weaker, and rough-turned

weaker even than the smooth-turned. The rough-turned specimens were about 18 per cent lower in endurance limit than those finished with the rouge polish. Similar results on the smooth-turned and rough-turned specimens were found with a very soft 0.02 carbon steel.

Effect of Overstress on Endurance Limit.—In order to determine whether stressing a specimen above its normal endurance limit would have a serious effect on the endurance limit under subsequent stresses, a number of different combinations of overstress and cycles of rupture were tried on a 0.49 carbon, sorbitic steel. For instance, one series of specimens was given 5,000 cycles of stress at a unit stress 10 per cent higher than its normal endurance limit. These specimens were then tested in the usual way to determine whether the over-

FIG. 5. COMPARATIVE PHYSICAL PROPERTIES OF STEELS UNDER TEST

stressing had changed the endurance limit. It was found that 10 per cent and 20 per cent of overstress applied 5,000 times, 29 per cent of overstress applied 1,000 times and 38 per cent of overstress applied 100 times did not reduce the endurance limit appreciably.

On the other hand, 35 per cent of overstress applied 1,000 times reduced the endurance limit about 4 per cent and 29 per cent of overstress applied 5,000 times reduced the endurance limit 11 per cent. It seems that a material may be able to withstand a considerable amount of overstress if the overstress is applied only a comparatively small number of times. Tests on a hard, high-carbon steel gave similar results to those above mentioned, the percentage of reduction being somewhat higher than for the soft steel.

Various Factors Influencing the Endurance Limit.

It is a well-known fact that the effect of subjecting steel to a tensile stress beyond the yield point is to raise the static elastic strength to a marked degree, as is illustrated by the strength of cold-drawn and cold-rolled steel. It was found in the case of a 0.18 carbon steel that the effect of such cold work was less marked on the endurance limit than on the static elastic strength, though some increase of the endurance limit was observed after cold working. Annealing of commercial cold-drawn screw stock was found to reduce its endurance limit.

Fig. 2 illustrates the effect of heat-treatment on the endurance limit. In the very soft condition of the pearl-

itic structure of the 0.93 carbon steel the material has an endurance limit of 30,500 lb. per sq.in. This can be increased by 84 per cent if the steel is given a sorbitic structure by heat-treatment, and by 221 per cent when it is given a troostitic structure. In general, a heat-treatment which raises the static elastic strength and the ultimate tensile strength raises the endurance limit also, but the increase in static strength is not a reliable indicator of the amount of increase in endurance limit.

In those cases in which the same steel was tested in a hard and a soft condition the results show that giving the material a sorbitic structure by heat-treatment may greatly increase the endurance limit without much sacrifice of ductility.

The results thus far obtained on eight different steels in reversed torsion indicate that the ratio of the endurance limit in torsion to the

endurance limit in bending is about 0.52.

With one very soft steel it was found that the computed stress at the endurance limit in bending was actually about 33 per cent higher than the proportional elastic limit in tension. This material was almost pure

FIG. 6. COMPARATIVE PHYSICAL PROPERTIES OF STEELS UNDER TEST

ferrite and the result indicates that homogeneity of structure is a valuable factor in giving a high resistance against fatigue. Results indicate that thorough annealing also produces a high ratio of endurance limit to proportional elastic limit. It is quite possible to have a high ratio of endurance limit to proportional limit, when both are low.

Only one nickel and one chromium-nickel steel were investigated. The results indicate that the alloy steels have somewhat higher endurance limits for the same ductility, as compared with plain carbon steels.

Distillation Studies of Nitric Acid and Sulphuric-Nitric Acid Mixtures—II

Equilibria in the System Water:Nitric Acid:Sulphuric Acid During Distillation at Various Pressures
—Graphic Study of the Phenomena of Distillation—Application of the Experimental Data
to the Preconcentration and Superconcentration of Nitric Acid

By PAUL PASCAL

With the experimental assistance of Mr. Garnier

Study of the Ternaries: Water, Nitric Acid Sulphuric Acid

THE addition of sulphuric acid to a nitric acid modifies the volatility of the latter greatly. The phenomenon may be pictured by assuming that the sulphuric acid forms, with the water of the mixture, a non-volatile hydrate in an enriched nitric acid solution. The variation in the boiling point of the mixture with the first addition of sulphuric acid is determined principally by this "enrichment" in nitric acid, only later does the increase in the concentration of the sulphuric acid intervene, and the boiling temperature then rises in all cases.

It may thus be foreseen that the first addition of sulphuric acid will raise the boiling point of weak acids and lower that of strong acids.

But the most regular and most manifest effect of the addition of sulphuric acid is a rapid enrichment in nitric acid of the vapors emitted during boiling, and in a progressive effacement and displacement of the maximum toward acids of low nitric content.

In the zone of acids poor in water the boiling point varies very little as long as the sulphuric acid content remains below 60 to 70 per cent, but the nitric acid vapor emitted is then colored strongly red by the products of dissociation of the acid, and the true boiling point is distinctly lowered by this disturbing factor.

There are shown in Table IV the results of our experiments at various pressures, acids having about the same sulphuric acid content being grouped together. A final series comprehends mixtures which were almost anhydrous and which boiled with a partial dissociation of the vapor, at temperatures certainly too low; we have, however, included them because of the interest they present in practical operation.

The results of all these experiments may be reviewed by plotting in triangular co-ordinates the contours of the surface of boiling points, of which the altitude of the different points is a measure of the corresponding boiling point. Figs. 5, 6, 7 and 8 hold for the pressures 317, 458, 570 and 760 mm. respectively; the apexes of the reference triangles, *N*, *H* and *S*, represent 100 per cent nitric acid, water and 100 per cent sulphuric acid.

The contour lines have been plotted every 10 deg., and there has been added in dotted line the contour through the highest point of the maximum boiling point line, which, depending on the pressure, corresponds to 96, 104.5, 112.1 and 121.5 deg. C. respectively. For aqueous sulphuric acid the boiling point data of Bryce

Cudleigh Burt [*J. Chem. Soc.*, vol. 85, p. 1339 (1904)] have been used.

The momentary lowering of the maximum boiling point on the addition of sulphuric acid to a nitric acid of 65 to 68 per cent is noticeable, as well as the disappearance of this maximum in acid of this strength to which about twice its weight of sulphuric acid has been added and the rapid variation of the boiling point for mixtures containing three times as much sulphuric as nitric acid, for a water content of 15 to 20 per cent

But these acids of rapidly varying boiling point are just those employed in the manufacture of nitrocotton and it is known how strictly interdependent are the water content and the degree of nitration. It is thus possible to see in our results a justification of Saposchnikoff's contention that the degree of nitration of the cotton is directly influenced by the nitric acid vapor pressure of the bath. In the region which interests us, a small variation in water content displaces the boiling point considerably and in the same way affects the partial pressure of the nitric acid; it is thus comprehensible that it may cause the nitrogen content of the nitrocotton to vary rapidly.

COMPOSITION OF THE VAPORS EMITTED

The concentration in nitric acid, of the vapors emitted by mixed acids boiling under normal pressure is represented by the ternary diagram, Fig. 9, in which have been given, every 10 per cent, the boundaries of the mixtures giving vapors of the same composition. Lowering the pressure displaces the curves scarcely at all, in the direction of a higher acidity.

The distribution of the vapor composition curves shows besides, at least for mixtures not too rich in water nor too poor in nitric acid, that the composition of the vapor depends solely upon the water content of the boiling mixture. When there is less than 30 per cent of water in the liquid, the vapor contains less than 10 per cent water, with relatively little decomposition products, while for weaker acids the strength of the vapors rapidly decreases.

GRAPHIC STUDY OF THE PHENOMENA OF DISTILLATION

Let us designate by *n* the locus of the points representing the mixtures which on distillation yield a vapor of concentration *n* (Fig. 10). During this distillation the representative point *P* of the liquid, located at each instant upon a different curve *n*, is displaced continuously along the segment *nP* which joins *P* with the point *n* on the line *NH*, representing the vapor which passes over. The line *nP* is thus, at each instant, tangent to the trajectory at the point *P*, so that the line of the route passed over by the representative point of

pose to call this the trajectory of distillation. It is at once apparent that through one point on the plan passes one trajectory of distillation, but only one; the system of these curves is thus formed by a series of lines which nest into one another without crossing.

Three curves worthy of note then present themselves in the plan of this figure:

1. Let us draw from a point n on the line NH a horizontal which cuts the corresponding curve n at M_0 . The locus C_0 of the points M_0 (Fig. 11) represents the locus of the points where the trajectory of distillation possesses a horizontal tangent; or, in other words, the moment when the boiling liquid passes through a maximum concentration of nitric acid.

2. Let us draw the locus C_1 , the intersections of the

straight lines Sn with the corresponding curves n . All the trajectories of distillation cut C_1 in such a manner that at the point of coincidence the tangent passes through the point S representing sulphuric acid.

But if a mixed acid is regarded as a mixture of 100 per cent sulphuric acid and a dilute nitric acid which it is desired to concentrate, curve C_1 divides the plan into two noteworthy regions. All the points of curve C_1 represent those mixtures which at the instant the distillation begins give off vapors of the same composition as the nitric acid it was desired to concentrate. The left-hand region thus contains all the weak mixtures, which at the beginning of the distillation give off vapors less rich than the initial nitric acid; the

FIG. 11. CURVES DIVIDING PLAN INTO REGIONS HAVING SPECIAL PROPERTIES

right-hand region, on the contrary, corresponds to mixtures giving off stronger vapors. Actually curve C_1 is very near curve C_0 .

3. Finally, let us draw from each point n on the side NH a tangent nT to the corresponding curve n . The locus of the points of contact T will be a third noteworthy curve C_2 . From what has preceded, all the points of this curve belong to the trajectories of distillation which are tangent to the corresponding curve n at this point; and at this moment the liquid will emit a vapor of the concentration n . But the form and the position of the curves n is such that they are not cut by the trajectories that are exteriorly tangent to them. On both sides of the point T the trajectory thus passes through points corresponding to emitted vapors of a lower composition than n .

The curve C_2 is thus the locus of representative points through which the liquid passes at the moment when it is emitting a vapor of maximum concentration. But the extremity of the tangent which sweeps the line NH turns back at the moment when its point of contact falls upon the curve C_2 , just when the concentration of nitric acid in the vapor passes through a maximum. The curve C_2 is thus equally the locus of the points of inflection of the trajectories of distillation; their concave side, turned toward the bottom in the region of weak liquids, turns up toward the top of the triangle in the region of more concentrated liquids.

The curve C_2 , moreover, divides the plan into two remarkable regions:

1. The region adjacent to the apex H , containing points representing mixtures of which the vapors pass through a maximum of acidity during distillation.

2. The opposite region, containing points representing mixtures of which the vapors emitted during distillation have a constantly decreasing acidity.

Fig. 12 gives several examples of trajectories of distillation. It is easy to verify that if the system of trajectories is superimposed on the system of isotherms (Figs. 5, 6, 7 and 8) the point representing the liquid being distilled is displaced continually toward an increasing boiling point.

The relative location of the three curves C_0 , C_1 and C_2 shows also that the moment when the vapors emitted possess a maximum acidity does not in general correspond with the moment when the liquid passes through a maximum nitric acid acidity. This phenomenon does not occur except when the original mixtures are represented by points on C_2 or to the left of C_2 .

It is to be noted, finally, as follows from their definition, that the three curves C_0 , C_1 and C_2 run together at a point on the line HN corresponding to that of the maximum boiling point.

Application of the Preceding Study

The curves of Fig. 3 permit the operation of the apparatus used for preconcentrating weak nitric acid from the arc process to be accounted for.

Imagine that at the base of one of these apparatus a relatively weak acid is boiled, represented by the point L in Fig. 13. It will give off a vapor more

FIG. 12. TYPICAL TRAJECTORIES OF DISTILLATION

dilute, represented by V , and will consequently leave behind a residual liquid L_1 which is richer and boils at a higher temperature L_2 .

If the vapor emitted enters a plate column, it condenses on one of the plates to a liquid layer which boils at a lower temperature L' and which as a consequence emits a vapor still less acid. Thus, by the operation of the column the vapors circulating in the upper part of the column will become poorer and poorer in acid, the residual liquids more and more concentrated.

A time will come, however, where the composition of the boiling liquid approaches that of the maximum, the vapors condensed upon the different plates will be nearer and nearer the composition of the boiling

liquids; the column will become insufficient and 68 per cent HNO_3 will not be attained in the residual acid, at least without raising to an excessive point the strength of the weak liquors.

The very flattened shape of the dewpoint curve fortunately makes it possible to employ the usual columns for an already very extended preconcentration, and at the plants of Rossi, where the process has been carried out with success, acids of 60 per cent strength are easily obtained when starting with the very weak acids

FIG. 13. DISTILLATION CURVE FOR NITRIC ACID

from the Pauling arc process. This fortunate circumstance gives a great interest to preconcentration, still too little extended, which offers great economy in fuel.

It is indeed of interest to evaporate an important part of the water contained in the weak acid, of which the heat of dilution is low; there is thus avoided the difficulty of making the same separation later from the dilute sulphuric acid which results from the final concentration of the nitric acid and which must return to the cycle after its strength is raised, at the expense of much coal used at much higher temperatures.

A weak nitric acid, strengthened, if need be, by preconcentration, may be transformed by distillation into concentrated and even anhydrous acid, if it is mixed beforehand with a sufficient amount of sulphuric acid.

As is known, the operation may be carried out in retorts, or better, in columns, made of towers filled with acid-proof material, down which runs the mixed acid, while superheated steam is injected at the base. We will examine in turn the theory of these two processes.

Let us treat this question in the most general way. To obtain a relatively concentrated nitric acid by distillation of any mixture of sulphuric and nitric acid whatever, the operation may be carried out in two different ways, depending upon the composition of the original mixture. (See Fig. 14.)

Let us suppose, first, that the point representing the original mixture is to the left of the curve C_2 ; there is collected, then, by the complete condensation of the vapor a nitric acid whose acidity (the original value given by the tangent m_0M_0 to the trajectory of distillation) constantly increases up to the end of the operation (total distillate). When, for example, the point representing the residual acid reaches the position M_1 , the condensed acid has the total composition m_1 , and the weight collected is the fraction $M_1M_0 \div M_1m_1$ of the original mixture.

At M_2 , situated on the curve C_2 , the distilling vapors have the maximum concentration, but the same is not yet true of the total condensed acid, represented by m_2 , for beyond this point the concentration of the vapors drops slowly enough to compensate for the initial dilution of the distillate. The concentration m_3 of the acid collected is not reached until the boiling liquid reaches

the point of contact M_2 on the trajectory of distillation. This is the time to stop the distillation, for from this moment the tailings will cause the concentration of the total distillate condensed to drop toward the limiting value M_3 , given by the intersection of NH and the straight line SM_0 .

When, on the contrary, the representative point M' , is to the right of the curve C_2 (and this is the case for the mixtures generally denitrated), the acid distilled, with an initial concentration m' , ($m'M'$, tangent to the trajectory of distillation at M') decreases constantly in strength to the minimum value m'' , determined by the straight line SM' .

For mixtures weak in nitric acid, as acids to be denitrated always are, the point m' , is always located very low; it is thus necessary to cut off before the end of the distillation. This is done the moment when the increase in the amount of acid collected appears to be neutralized by its progressive dilution. A good yield of concentrated acid is never obtained.

We will state to begin with that the system of curves n almost coincide at different pressures, with a mere tendency for the vapors to become richer when the pressure is lowered (and consequently when the temperature drops). It consequently results that, throughout their heating, the mixed acids emit a vapor which varies little in composition and becomes only a little less rich in nitric acid as boiling point is approached.

The mixtures of weak nitric acid and concentrated sulphuric acid, or better yet waste acids, which are

FIG. 14. CONCENTRATION AND DENITRATION IN RETORT

handled in towers, contain generally, roughly: HNO_3 , 15 per cent; H_2O , 15 per cent; H_2SO_4 , 70 per cent.

They are represented by the point A (Fig. 15). In its rapid descent over the packing or the plates of the tower, the liquid is but imperfectly in equilibrium with the surrounding vapors. Also, the concentrated vapors emitted by the distilling liquid are diluted by the weaker vapors from the lower part of the tower; instead of an acid C_0 , of more than 95 per cent, passing over, somewhat stronger even than the acid determined by the original tangent At to the trajectory at A, the apparatus gives in regular operation an acid whose strength corresponds only to the point C.

When the distillation is carried out in a kind of recti-

fying apparatus of silicon iron,³ heated externally, the "denitrated" acid depends upon the operating temperature T of the bottom of the column. If TBB' is the isotherm corresponding to the surface of boiling points, the acid run out at the base of the column is generally incompletely denitrated, and its representative point B , situated at the intersection of AC and the isotherm, permits a determination of the fraction $B'B_1 \div BB_1$ of nitric acid lost.

When, on the other hand, the distillation is made in towers into the base of which live steam is injected, a

FIG. 15. CONCENTRATION AND DENITRATION IN A TOWER

much better denitration may be obtained, for the same heat consumption, without any appreciable diminution in the strength of the nitric acid separated.

The acid which distills is again represented by a point near the end of the tangent At , but this time there is introduced into the tower the acid A plus a certain amount of water vapor (in practice 10 to 12 per cent of the weight of original acid). The sum of the liquids treated is then represented by the point A' on the line AH .

But now, contrary to the progress of the "dry" distillation of a moment ago, the point B' of the denitrated acid can be brought to occupy the extremity B' of the isotherm of the base by a judicious choice of the temperature and amount of steam used. In this way a perfectly denitrated residue is obtained, without, however, diluting the recovered nitric acid. It is common practice to produce 92 per cent acid in this way, starting with the acid mentioned above and leaving as residue a sulphuric acid of 62 per cent H_2SO_4 .

This easy carrying over of nitric acid by steam, from sulphuric acid mixtures, is moreover a property well known to analysts who determine the nitric acid of mixed acids by the difference in acidity of the liquids, first of the original, then of the residue after this has been diluted with water and evaporated several times.

I will add in conclusion that all of the preceding study may be applied in all cases of distillation of ternary mixtures of which only two constituents are volatile under the conditions of the experiment.

Various Methods for Hardening High-Speed Steel

BY A. H. D'ARCAMBAL

Metallurgist, Pratt & Whitney Co., Hartford, Conn.

IN THIS paper I will state briefly the advantages and disadvantages of different hardening methods for high-speed steel, proposed in the 20 years which have intervened since Taylor and White made their recommendations.

SALT BATH HARDENING

Salt bath hardening was first introduced in this country in 1902. Ordinarily, barium chloride is the salt used and the operating temperature is from 2,000 to 2,100 deg. F. (1,093 to 1,149 deg. C.) Graphite crucibles are used for holding the salt, the life of these crucibles being from six to eight heats. The tools to be hardened are immersed in the hot liquid and the tools permitted to remain until the entire mass of the tool has attained the temperature of the bath. These tools are then usually oil-quenched, and drawn to from 400 to 600 deg. F. (204 to 316 deg. C.) in oil, depending upon the kind of tool.

No scaling takes place by this method, thus producing a cleaner tool than in muffle furnace hardening, but the method has the following disadvantages: (1) The quenching temperature is too low. (2) Soft scale is sometimes produced. (3) Blistering and pitting sometimes occurs. (4) Pots are very short lived.

It is a well-known fact that to obtain the highest degree of red-hardness, partial austenization must take place. This means quenching from a temperature of 2,200 deg. F. (1,204 deg. C.) and upward; indeed, the higher the quenching temperature above 2,200 deg. F. (1,204 deg. C.) up to about 2,350 deg. F. (1,288 deg. C.) the greater the effect called "secondary hardening"—the added hardness gained by tempering quenched steel. We have heated small test-pieces of high-speed steel 1½ hours in a barium chloride bath at 2,100 deg. F. (1,149 deg. C.), but the microstructure was the same as when left in the bath just long enough for the heat to soak through.

Blistering and pitting of tools heated in a barium chloride bath are said to be due to particles of the graphite crucible which have broken loose coming in contact with the tools and sticking to them. Sometimes these blisters or beads drop off, leaving pits. The longer service the bath has seen the more loss is suffered through this blistering and pitting.

A graphite pot lasts only from six to eight heats, making this method of hardening quite a costly one. A new salt is now being introduced for the hardening of high-speed steel, which can be maintained at a temperature of 2,200 deg. F. (1,204 deg. C.), thus being superior to the barium chloride bath. The container used is a graphite crucible with a cast-steel liner. In this way the steel pot is protected from the flame, and there is no danger of blistering or pitting from particles floating through the bath.

PACK HARDENING

Pack hardening consists of packing the high-speed tools with charcoal in a suitable container. The container is then luted carefully with clay, and the whole placed in a furnace, the temperature brought up to around 2,200 deg. F. (1,204 deg. C.) and held there a

considerable length of time. Tools are then removed, oil-quenched or air-cooled.

This method gives a tool free of scale, but has the following decided disadvantages: (1) Quenching temperature is too low, and (2) tools are carburized. We obtained the temperature of some test-pieces with an optical pyrometer just before they were removed from the pack, and found the temperature to be about 2,050 deg. F. (1,121 deg. C.), although the furnace temperature was 2,200 deg. F. (1,204 deg. C.), and they had remained 1½ hours at heat. Scleroscope tests and micrographs verified this temperature. Furthermore test-pieces showed a gain of 0.40 per cent carbon on the surface after being given the pack treatment.

I have been informed by two different men who attempted this method that at times the cutting edges of the tools melted, due either to the higher carbon content of the surface of the tools or to the tools coming in contact with each other. One other experimenter tried to use a cast-iron box for packing, but as cast iron melts at about 2,200 deg. F. the results can well be imagined. Carborundum powder has been suggested as a substitute for charcoal for a packing material, as the former would not carburize the steel. In the writer's opinion, however, high-speed tools treated in this way would be inferior to tools heated in the semi-muffle furnace, because the steel would have to remain at a high temperature for a long time when pack hardened, thus producing a coarse-grained structure.

LEAD BATH HARDENING

A lead bath was tried quite extensively about 10 years ago for heating high-speed tools, but the method did not prove a success. At 2,200 deg. F. the vapor pressure of lead is about 20 mm. of mercury, so that severe volatilization will inevitably ensue. It is also quite a problem to find pots to hold the same. Difficulty is also experienced in controlling the time of immersion, as lead is a very rapid heating medium. A metallurgist for one of the large tool steel mills in England told me recently that a large amount of high-speed steel was hardened in his country by the lead bath treatment. He stated that they were able to obtain a very pure grade of lead and could operate at a temperature of 2,300 deg. F. (1,260 deg. C.).¹ His method for hardening a 1-in. high-speed hand reamer would be to preheat to 1,500 deg. F. (816 deg. C.) in a muffle furnace, then transfer the tool to the lead bath whose temperature was 2,350 deg. F. (1,288 deg. C.), hold there 15 seconds and cool in an air blast.

SEMI-MUFFLE FURNACE HARDENING

Most of the high-speed steel hardened in this country is heated in semi-muffle furnaces, oil or gas fired. It is always advisable to have these furnaces equipped with pyrometers, using noble metal couples. The optical pyrometer is also satisfactory for controlling these high-temperature furnaces.

Work to be hardened should be preheated to 1,500 to 1,600 deg. F. (816 to 871 deg. C.), and when thoroughly heated through at this temperature, transferred to the high-temperature furnace, whose temperature is higher than the desired hardening heat. The tool is left in this furnace until the cutting edges have attained the proper temperature—about 2,300 deg. F. (1,260 deg. C.)—and the material then quenched. Soaking at the high tem-

perature is to be avoided, as it coarsens the grain and is likely to "burn" the steel. In such practice the time factor is evidently just as important as the temperature. Quenched tools are then drawn to the desired temperature. One great advantage of this method of hardening is the high temperature attainable, thus producing the greatest degree of red-hardness and almost complete solution of the carbides. The disadvantage is that the tool scales to a degree, which can be reduced to a minimum by a thorough preheating and the proper mixture of fuel and air in firing the high-temperature furnace. Large high-speed tools have been very successfully hardened by using two preheating furnaces; the first is maintained at a temperature of about 1,100 deg. F. (593 deg. C.) and is used as a stock furnace. The temperature of the second preheater is 1,700 to 1,800 deg. F. (927 to 982 deg. C.). The material will not scale in the first preheating furnace; while the steel will oxidize in the second preheater, it requires less time to bring it to heat, thus reducing scaling to the least possible amount.

Synopsis of Recent Chemical & Metallurgical Literature

Liberation of Ammonia From Coal and Coke.—At the recent annual meeting of the Institution of Gas Engineers of Great Britain, A. C. Monkhouse and Prof. J. W. Cobb reported the results of experiments undertaken by them to determine the influence of atmosphere upon the products of carbonization and its bearing upon the production of ammonia from coal. A complete report of the investigation appeared in the Oct. 21, 1921, issue of the *Iron and Coal Trades Review*. The work was especially directed toward the comparative behavior of nitrogen, hydrogen and steam in influencing the further yield of ammonia when carbonization at a low temperature (500 deg. C.) had been already effected. On carbonizing coal the authors found that the percentage of the total nitrogen of the coal obtained as ammonia is 10 to 25 per cent. The greater portion—40 to 80 per cent—is left in the coke; the remainder is found as free nitrogen and cyanogen in the gas, and a little in the tar. The liberation of ammonia in carbonization processes has been shown to be affected by various factors, such as: (1) *The Rate of Distillation.*—The slower the rate of distillation the more nitrogen is usually obtained as ammonia. (2) *The Nature of the Coal.*—Generally speaking, the older the formation of the coal geologically the smaller is the proportion of the total nitrogen obtained as ammonia. (3) *The Temperature of Distillation.*—The higher the temperature of distillation the less nitrogen is left in the coke. Temperatures above 500 deg. C. are necessary for a good yield of ammonia. In complete gasification with air and an excess of steam, as in the Mond process, the yield of ammonia is much higher than in carbonization—60 to 70 per cent. Our method was to take a particular coal and to coke it at three definite temperatures—500, 800 and 1,100 deg. C.—so preparing soft, medium and hard cokes. The action of hydrogen on these three cokes was then determined at three different temperatures—600, 800 and 1,000 deg. C. In order to differentiate between any specific action of hydrogen on the nitrogen compounds and the influence of an inactive gas, similar experiments were made using nitrogen instead of hydrogen. Comparison with steam followed.

A New Etching Agent for Chromium and Tungsten Steels.—Karl Daeves, in *Stahl und Eisen*, Sept. 8, 1921, p. 1,262, emphasizes the advantages of potassium ferricyanide as an etching reagent for Cr and W steels, first proposed by K. Honda and T. Murakami. According to the Japanese authors, there are three carbides in Cr steels—namely, α -carbide (Fe_3C), β -carbide (Fe_2C) and γ -carbide

¹At this temperature the vapor pressure of lead is nearly 50 mm. of mercury (see J. Johnston, *J. Ind. Eng. Chem.*, vol. 9, p. 873 (1917)).

FeC₂Cr₂C. A mixture of 10 g. potassium ferricyanide and 10 g. KOH in 100 cc. water acts as follows: α -carbide is attacked even in the cold, giving a brown to blue coloration; β -carbide is attacked only when hot, and γ -carbide is not attacked. High-speed steel with over 12 per cent tungsten contains the compound Fe₂W, which is easily attacked by the cold reagent, giving a brown to blue coloration.

Dr. Davies has also made further studies on the advantages of a potassium ferricyanide etching reagent and recommends the following solution: 20 g. potassium ferricyanide, 10 g. sodium hydroxide, 100 g. water. The following table summarizes the results found on various analyses:

Sample	Analysis, per Cent			Amount of the Etching Reagent	
	C	Cr	W	Cold Reagent	Hot Reagent
1	1.13	9.3		Coloration of the surface	Same as for cold reagent, but deeper (black) coloration
2	1.94	8.2		None	None
3	1.24	9.4		None	Grain boundaries slightly brown
4	0.3	3.00		Coloration of the surface	Same as for cold reagent but deeper
5	0.34	3.23		Traces of the surface colored	None
6	0.4	3.13		None	None
7	0.24	11.3		Coloration of the surface, small grains at the grain boundaries	None
8	1.76	1.1		None	Secondary cementite colored blue, pearlite light yellow
9	1.0	1.12		None	None
10	1.24		0.3	None	Cementite lamellae in the pearlite colored yellow to blue
11	1.13		1.2	None	None
12	0.3	4.1	12.2	Small and large carbide grains colored	Same as for cold reagent, but deeper coloration
13	0.2	4.0	14.0	None	None

This reagent is not satisfactory for pig iron, carbon and Ni-Cr steels.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 1 cc. to the Commissioner of Patents, Washington, D. C.

Electrical Heating Alloys.—An electrical heating element made of alloy steel containing iron, chromium, silicon and cobalt has been patented by Percy A. E. Armstrong, of Loudonville, N. Y. The chromium content of this alloy can be varied up to 30 per cent, the silicon to 7 per cent and the cobalt to 5 per cent. It is claimed that the alloy has considerable resistance to oxidation and to acids and similar corrosive agents. It therefore appears to be adapted for heating corrosive liquids. (1,383,740; July 26, 1921.)

Production of Ethyl Alcohol From Coke-Oven Gas.—Byproduct coke-oven gas or other gas containing ethylene and from which the tar, ammonia and light oils have been removed is treated to remove hydrogen sulphide, water and carbon dioxide, and is then scrubbed by causing it to bubble through hot concentrated sulphuric acid. The ethyl hydrogen sulphate resulting from the ethylene is withdrawn from the scrubbers, while the gas passes to the distribution mains for commercial use. By mixing the ethyl hydrogen sulphate with a definite quantity of water and subjecting the mixture to heat for a predetermined length of time, the requisite conditions are obtained for the formation of alcohol. The reaction yields its maximum production of alcohol when the mixture is heated in a closed vessel under a temperature ranging between 100 and 120 deg. C. The reaction develops rather slowly but is ordinarily completed in 50 to 60 minutes. It appears that the process has formerly been carried out without allowing the requisite time for completing the reaction and there has been no control or limitation of the volume of water or steam added. As a result of the latter practice, the relatively small quantity

of alcohol formed was usually greatly diluted, hence recovered with more difficulty. It is proposed to limit the volume of water to 50-70 per cent of the combined volume of acid and sulphate.

Another important factor bearing on the yield of alcohol is the concentration of the ethyl hydrogen sulphate in the scrubbers. In the process described in this patent, the acid is withdrawn when the ethyl hydrogen sulphate reaches a concentration between 10 per cent and 20 per cent by weight of the sulphuric acid. When this concentration exceeds 30 per cent, the subsequent dilution and treatment of the concentrated ethyl hydrogen sulphate produce ether in substantial quantity, which increases with the concentration of the ethyl hydrogen sulphate. (1,385,515; Chas. A. Basore, of Auburn, Ala., July 26, 1921.)

Process and Apparatus for Electrolysis of Sodium Chloride Solutions.—According to a recent invention of A. H. Hooker, an aqueous solution of sodium chloride carrying an excess of salt in the solid phase is introduced into the electrolytic cells in constant volume per unit of time. The quantity of salt thus supplied in solid phase is not quite sufficient to maintain the brine within the cell in a saturated condition at the operating temperature. In the past it has frequently been proposed to add an excess of solid salt, or to maintain a permanent supply of such salt within the cell, but it is well known that under such conditions the diaphragm will rapidly become clogged. In the present process the brine within the cell is kept safely below the saturation limit.

In the accompanying drawing 2 is the brine storage tank, 3 the salt hopper, 4 the mixing and agitating tank, 5 the electrolytic cells and 6 the level regulating device. The brine flowing through the power-driven metering device 8 is directed over the end of the worm conveyor 13, where it washes the salt out of the worm as fast as it is fed forward and carries it through the screen 15 and chute 16 into the mixing tank. There is, therefore, in the operation of this device a fixed relation between the displacement of the brine meter and the salt feed. This ratio may be adjusted by the proper choice of sprockets 10 and 12.

By means of the pump 17 and the pipes 21 and 24 a rapid circulation of the salt suspension is maintained. The mixture in the tank is therefore kept in violent agitation and the undissolved salt is maintained in suspension during its flow to the level regulating tank 6 through pipe 21 and its return through pipe 24.

Above each cell 5 is provided a feeding orifice or nozzle 27 of special design. The hydrostatic head upon this orifice

is determined by the level of the liquid in tank 6. This may be adjusted as desired by changing the effective height of the overflow pipe 23. As long as the level in the tank 6 is maintained constant, a uniform quantity of brine carrying with it any desired excess of suspended salt is fed into the cells. The circulating system and the means employed for maintaining the uniform feed are covered by patent 1,388,474 issued to Thomas L. R. Lyster and Kenneth E. Stuart of Niagara Falls, N. Y., assignors to Hooker Electrochemical Co. (1,388,496; Aug. 23, 1921.)

Book Reviews

METALLURGIE GENERALE. By *Léon Guillet*, 528 pp., with 335 illustrations. Paris, France: J. B. Baillière et Fils. Price 40 fr.; bound, 50 fr., 1921.

The publishing house of J. B. Baillière et Fils of Paris has undertaken to publish a technical encyclopedia which will be grouped into five classes—namely, Mining and Metallurgy, Electricity, Mechanics, Civil Engineering, and Chemistry, comprising respectively 43, 35, 30, 30 and 54 volumes, each volume to contain from 300 to 700 pages. This great work is to be carried out under the editorship of Léon Guillet for Mining and Metallurgy, André Blondel for Electricity, Léon Lecornu for Mechanics, A. Mesnager for Civil Engineering and Camille Matignon for Chemistry.

The collection of 192 volumes is to be published under the auspices of the Société d'Encouragement pour l'Industrie Nationale, the Society of Civil Engineers of France, the Union of the Mining and Metallurgical Industries, the Union of the Electrochemical Industry, the Society of Chemical Industry, the Hydrotechnic Society and other scientific and industrial institutions.

The fifty-four volumes devoted to chemistry are:

Thermochemistry	Metallurgical Analysis of Iron
Chemical Equilibrium	Combustibles and Their Distillation
Raw Materials in the Chemical Industry	Coal-Tar Distillates
Heating and Power in the Chemical Industry	Petroleum
Installation of Chemical Plants	Paints
Installation of Chemical Laboratories	Varnishes
Patents and Trade Marks	Powder and Explosives
Material Handling	Perfumes
Crushing, Pulverizing	Plastic Materials
Mixing and Agitating	Bleaching
Filtration	Fats
Concentration, Evaporation, Drying	Cellulose and Paper
Mineral Acids	Oenology
Industrial Bases	Brewing
Potash	Distillation
Sodium Nitrate	Sugar
Phosphates	Rubber
Electrochemistry	Tanning Extracts
Electrometallurgy	Tanning
Minor Chemical Industries	Resins
Precious Metals	Food Products (2 vols.)
Lime, Cement	Colloidal Chemistry
Glass	Pharmaceutical Products
Ceramics	Dyes
Porcelain	Waste Disposal
	Fertilizers
	Refrigerating
	Chemical Industry Hygiene

Of the forty-three volumes devoted to mining and metallurgy the following thirty-three volumes are devoted to metallurgy:

General Metallurgy	Chemical Analysis of Metallurgical Products
Fuels	Thermal and Chemical Treatments
Refractories	Welding and Soldering
Pig Iron	Electroplating
Bessemer Steel	Forging and Rolling of Steel
Open-hearth Steel	Forging and Rolling of Metals Other Than Steel
Crucible and Electric Steel	Casting
Ferro-Alloys	Drawing
Properties and Uses of Ordinary and Special Steels	Machining
Copper, Lead and Nickel	Foundry (2 vols.)
Zinc, Tin, Antimony and Mercury	Installation of Metallurgical Plants
Aluminum, Magnesium, Sodium and Calcium	Technical Organization of Metallurgical Plants
Gold and Silver	Commercial Function of the Metallurgical Industry
Platinum Group Metals	Economic Situation of the Metallurgical Industry
Radium	
Metallurgical Physics	
Metallurgical Chemistry	
Testing Metallurgical Products	

Métallurgie Générale, by Prof. *Léon Guillet*, is the first of the series on Metallurgy. This volume of 528 pages with 335 illustrations deals specifically with generalities on the extraction and refining of metals. It comprises twenty-one chapters, the following being a brief outline of the subject covered by each chapter:

In the chapter on classification of metallurgical operations (pp. 1-11) he defines the dry, wet and mixed processes and mentions their application to some of the most important ores.

Roasting and calcining are described under two main

classes—namely, those without and with chemical modification (pp. 12-32).

In the chapter on physicochemical laws in roasting and calcining (pp. 34-67) after enunciating Berthollet's eight laws on thermochemistry and the principle of maximum work, he dwells at length on Le Chatelier's thermodynamic laws as applied to metallurgy. The practical applications of these laws are described and are also diagrammatically illustrated.

After a brief description of the classification of the roasting and calcining apparatus, according to the fuel used (solid, pulverized, liquid and gaseous) and of the two main types—namely, direct heating and reverberatory (including electric heating)—(pp. 68-86) he describes and illustrates the most modern apparatus used under the two main classes of roasting and calcining without and with chemical modification (pp. 87-128) and concludes with a concise discussion on the selection of the appropriate apparatus (pp. 130-140).

Like roasting and calcining, fusion is described under the two main classes—namely, without and with chemical modification (pp. 141-200).

The chapter on the physicochemical laws applied to fusion (pp. 201-249) contains discussions and diagrammatic illustrations of fusion with the formation of two liquid layers and of fusion with one liquid and one solid layer. Classical equilibrium diagrams of alloys and reducing fusion with gaseous and solid reducing agents are also discussed.

Chapter VII contains a well-illustrated description of the different types of modern fusion apparatus and also concise outlines of charging and pouring for the different furnaces (pp. 250-313).

Vaporization is described under the two headings of vaporization without and with chemical modification (pp. 314-320). The physicochemical laws of vaporization are touched only briefly (pp. 321-322). The description of volatilization apparatus (pp. 323-335) is limited mostly to mercury and zinc furnaces, with brief mention of special furnaces for distilling alloys and amalgams.

The chapter on electrometallurgy (pp. 336-353) describes the principles of electrothermic operations without and with chemical modifications, giving also brief outlines of the applications to electric pig iron, alloys and aluminum.

In chapter XII he outlines and illustrates profusely the different types of modern electric furnaces and their adaptability for particular uses (pp. 354-384).

Chapters XIII (pp. 385-396) and XIV (pp. 397-416) deal with metallurgical wet method—namely, solution, precipitation and amalgamation—and with the apparatus used in these operations.

Chapters XV (pp. 417-430), XVI (pp. 431-443) and XVII (pp. 444-452) deal with electrolysis with insoluble and soluble anodes, with the physicochemical laws of electrolysis and with the electrolytic apparatus.

Chapter XVIII (pp. 453-468) summarizes the appropriate treatment for native metals and for the main groups of ores such as: oxides and carbonates, silicates, sulphides and arsenides.

Chapter XIX (pp. 469-489) describes pouring methods, faults of ingots and industrial methods used for improving the quality of the ingots.

Chapter XX (pp. 490-499) deals with the classification, properties and uses of metallurgical slags.

In the last chapter the author passes briefly in review the utilization of metallurgical gases, their purification, especially by the application of the Cottrell process, and the utilization of the precipitated dust.

Of special value are the chapters on the metallurgical apparatus, in which he dwells mainly on the most recent practice, and the chapters on the various physicochemical laws as applied to metallurgy, in which he has embodied the theories and practical conclusions of the past and present leading metallurgists.

The long experience of Mr. Guillet as professor of metallurgy and as editor of the *Revue de Métallurgie* has enabled him to give in this introductory volume a clear insight of the metallurgical art and of its present status.

J. S. NEGRU.

Current Events

in the Chemical and Metallurgical Industries

More Plants Increasing Operations

Rubber. The Kelly-Springfield Tire Co., Cumberland, Md., is arranging to place its local plant on a full-time operating basis at an early date, replacing a 4-day schedule operative for some time past. Employment is now being given to close to 1,000 workers as compared with a normal force of 1,165 men, and operatives now on furlough will be taken back gradually.

The Miller Rubber Co., Akron, Ohio, is increasing production at its plant, and since the first of the month about 2,000 employees have returned to the mills.

The Goodyear Tire & Rubber Co., Akron, Ohio, is planning for the resumption of a three-shift basis of production at its plant by Jan. 1. Night shift operations will be resumed at an early date.

The Stanwood Rubber Co., Newark Ave., Elizabeth, N. J., recently reorganized, is planning for the resumption of operations at the local plant on Jan. 15, following a shut-down of a number of months. Improvements will be made and machinery set up at once.

The Firestone Tire & Rubber Co., Akron, Ohio, is increasing operations and adding to its working force.

Ceramic. Practically every general ware pottery at Chester, W. Va., and vicinity is now being operated at capacity.

The McNicol Pottery Co., Clarksburg, W. Va., is increasing production to handle a volume of new orders.

The Briggs Co., Grand Ledge, Mich., manufacturer of facebrick, is developing record production at its plant, now averaging from 40,000 to 42,000 bricks per day. The company during the last month shipped more material than in any other similar period, totaling over 1,250,000 bricks. Advance orders are said to aggregate in excess of 800,000 bricks.

Glass. The Macbeth-Evans Glass Co., Marion, Ind., has resumed operations at its local plant, giving employment to about 500 operatives, or approximately 60 per cent of normal. The men will work in three 8-hour shifts. Additional employees will be added gradually to the force.

The Millville Bottle Works, Millville, N. J., is operating one plant at full capacity, and work will be commenced on a new factory for increased production at once.

The Mount Jewett Window Glass Co., Kane, Pa., controlled by the Interstate Window Glass Co., has been placed in operation, following a shut-down for almost a year past. Employment will be given to about 350 persons. The plant has been improved during the idle period. This is the seventh plant of the Interstate company to be placed in operation.

Iron and Steel. The Parryville (Pa.) Blast Furnace is arranging for immediate blowing in, following a shut-down for the past 6 months. More than 200 men will be employed.

The Lufkin Foundry & Machine Co., Lufkin, Tex., one of the largest industries in that section, will soon resume production on a full-time basis, following a curtailment for some time past.

The Midvale Steel & Ordnance Co., Philadelphia, Pa., is operating its different plants on an average of 50 per cent of normal, with bulk of activity at the Cambria mills.

The Harrisburg Pipe & Pipe Bending Works, Harrisburg, Pa., is operating at full capacity in the steel department at its works. In other branches production is now around 80 per cent, with prospects of early increase.

The Jones & Laughlin Steel Co., Pittsburgh, Pa., is now operating seventeen mills at its Woodlawn, Pa., works, for the first time in several months. A number of the mills resumed on Dec. 6.

Tin Plate. The American Sheet & Tinplate Co., Martins Ferry, Ohio, has placed four more mills in operation, making nineteen mills in service at the present time out of a

total of twenty-three. The company has placed every hot mill in operation at its New Castle, Pa., plants for the first time in more than a year, bringing the production up to a point of 100 per cent, or sixty mills. Several hundred additional men are being employed. This schedule of operation will be continued for an indefinite period.

Peat Gasoline Process Declared Fraud

In the case of Doolittle vs. Enricht, the trial of which was discussed at some length on p. 1109 of our Dec. 14 issue, the plaintiff was awarded the full amount invested in stock of the Enricht Peat Gasoline Co., Inc., plus interest.

In making his charge to the jury, Judge Lewis J. Smith stated that the main point in the case was whether or not Mr. Enricht could produce gasoline from peat by his process. To find for the plaintiff the jury would have to satisfy itself that representations were made, that they were fraudulent and that the defendant knew they were fraudulent. The measure of damage would be the amount paid by the plaintiff, \$1,000, less the present value of the stock, plus interest. Accordingly the verdict means that in the jury's opinion, the process was a fraud and that the stock is worthless.

During the latter part of the trial it was brought out that the suction-pressure pump was not produced in court with the rest of the apparatus but remained in Mr. Enricht's car until demanded by the experts. They noticed a piece of metal tubing on the piston rod of the pump which limited the stroke and demanded that the pump be taken apart. Mr. Enricht said that this was not possible. Then followed the peculiar actions noted last week which make it appear probable that gelatine capsules of some sort containing gasoline were concealed in the base of the pump, although this was denied by the defendant. In view of these facts at the conclusion of the trial, the attorney for the plaintiff moved that Mr. Enricht be held for perjury and contempt of court. This was denied because of a pending criminal action but the judge granted a motion by the District Attorney to increase the bail and fixed the sum at \$10,000, stating that Mr. Enricht had disobeyed the order of the court and that consequently he was not disposed to feel lenient. Mr. Enricht went to jail while the bail was being obtained.

New Oil Companies Organized

During the month of November, a total of seventy-one new companies was organized in different branches of the petroleum industry, with a capitalization of \$50,000 or larger. The total indicated investment was \$60,129,000, as compared with \$83,450,000 in the preceding month of October, and \$266,190,000 in the corresponding month of 1920. The aggregate indicated investment for the 11 months of the present year stands at \$1,190,042,600, divided among 878 companies, as against an amount of \$2,677,134,700 for the same period of 1920, representing the gross capitalization of 2,418 companies formed in this time.

Chemical Companies Organized

During the month of October thirty-five new companies were organized with a capital of \$50,000 or more, to engage in the chemical and affiliated industries, with indicated capitalization of \$6,300,000 for all organizations. This compares with the formation of twenty-six such companies in the preceding month of October, with a combined capitalization of \$6,675,000. In the same month of a year ago, the indicated capitalization of new companies was \$50,050,000. For the 11 months of the present year, the total indicated investment in new chemical companies stands at \$104,815,000, as against \$230,517,000 for the same period of 1920.

Marshal Foch Made Honorary Member of Engineering Societies

Extolled as a fellow engineer who has "directed a greater mass of human energy than any other man," Marshal Foch, at an elaborate ceremony Dec. 13, significant of the advancing movement to promote international peace through the furtherance of engineering ideals, was placed at the head of the honor roll of the organized engineering profession of the United States. In electing Marshal Foch to honorary membership in the four national engineering societies the engineers broke all precedent. The organizations whose governing boards unanimously conferred this distinction upon Marshal Foch were the American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers and the American Institute of Electrical Engineers.

The ceremonies were held in the auditorium of the Engineering Societies Building. J. Vipond Davies, president of the United Engineering Society, presided and made a four-minute speech, after which Colonel William Barclay Parsons delivered an address in French. Formal presentation of the certificate of honorary membership was made by G. S. Webster. Marshal Foch responded in part as follows:

It was due largely to engineering and the engineering industry that the war was brought to a successful conclusion. To the engineering profession also we are indebted for many great lessons which will be vital to mankind in the future. The armies could not have done a great deal without the effort of the engineer. Success was made possible to a great extent by the industry of the people at home, but when it became a question of decision, when the decisive moments arrived, the engineer stood out as an essential factor in complete triumph. What would have become of the armies without the technical training, without the professional knowledge, which you have exercised for the Allies and which enabled us to lead our armies in the field, to feed them, to protect them, and to facilitate their advance quickly and decisively? It is for these reasons that I am pleased to find you here today, to receive from you so splendid a welcome and to express my gratitude and the gratitude of France, as well as the recognition of my countrymen for the tremendous sacrifices made by you and the men of your calling. I am grateful to you for including me in your ranks as a member of the four great engineering societies of the United States. Believe me, this honor which you have conferred upon me I indeed appreciate and I shall cherish this event with the happiest memories.

Safeguarding Fumigation With HCN

The great drawback to the use of hydrocyanic acid gas has been offset, it is believed, by an achievement of the chemists connected with the Chemical Warfare Service. Since hydrocyanic acid gas possesses the quality of killing the eggs of vermin, in addition to being a very powerful disinfectant, it is held by the United States Public Health Service to be the most effective disinfectant which can be used for a variety of purposes. It finds one of its chief uses in the disinfecting of ships. The chief objection of its use has been the fact that it has no smell or taste and produces no discomfort when breathed. As a result a person breathing it has no warning until he collapses. This has led to many casualties. The Chemical Warfare Service, however, has found that by adding tear gas to hydrocyanic acid gas ample warning is given of its presence. The effect of tear gas is felt instantly, whereas hydrocyanic acid gas must be breathed for several minutes before there are serious results. The experiments indicate that the admixture of tear gas will make possible an extended use of this valuable disinfectant.

Bureau of Mines Increases Chemical Staff

The Bureau of Mines has authorized the employment of a chemical engineer to assist in its non-metallic work. He will be stationed at Reno, Nev. Two chemical engineers are to be added to the staff of the ceramics station at Columbus to do work on cement.

Factory Waste Legislation Not Imminent

No legislation attempting to deal with the pollution of streams will be recommended by the House Committee on Rivers and Harbors until after a thorough study has been made of the question. The committee expects to recommend legislation after the holidays intended to meet the oil nuisance caused by the discharge of petroleum wastes by ships. The committee probably will recommend that the Department of Commerce and the Chief of Engineers make a special study of the alleged injurious effects of wastes from chemical and other manufacturing plants, before undertaking to suggest legislation.

This conclusion was influenced in no small degree by the testimony of Secretary Hoover and by that of John I. Tierney, secretary of the Manufacturing Chemists' Association. Mr. Hoover urged strongly that present legislation be confined to the petroleum nuisance. An excerpt from the argument which was presented by Mr. Tierney is as follows:

Any consideration of the question of factory waste must take into account local conditions. A manufacturing plant may be the sole or principal support of a community, but would Congress be justified in closing its doors because its effluent made an angler's holiday afternoon less thrilling? That question was put to the Supreme Court of Pennsylvania and the court decided that operation of the coal mines contributed more to the general welfare than did fish life in the rivers affected. Whenever the problem arises in the interior the community in which the factory is situated may be depended upon to work out a solution much more satisfactory than could Congress, and Congress would do well to leave to the city councils and to the state legislatures the framing of ordinances and statutes to control in the particular cases needing attention. Indeed, it is a serious question whether Congress has the power to include the streams of the interior in any legislation upon this subject. The Supreme Court has determined time and again that the federal government has no ownership of, or jurisdiction over, non-navigable streams of a state, and that it has only a negative power as to the navigable rivers, which may be exercised only to prevent obstruction to navigation.

If Congress, nevertheless, enacts a law to prohibit plants located on navigable rivers discharging their effluents into the waters, while it is powerless to enforce similar prohibition as to factories on non-navigable streams, there will result unequal conditions among competitors in the respective industries. The practical aspects of the question, as well as the provision of the Constitution and the rule of law, should convince Congress that the safest and wisest course is to leave to the city councils and to the state legislatures the solution of this industrial problem, at least to the extent that it exists in the interior. And as stated above, information concerning the relation of factory waste to the pollution of harbor waters is so meager and uncertain that the wiser plan would be for Congress to direct an investigation to be made of that phase of the problem before drafting a measure to deal with it.

Regulations for Transportation of Carboys

The regulations for the transportation of containers which have been used in the shipment of flammable or other dangerous articles have been amended by the Interstate Commerce Commission so as to read as follows:

Empty cylinders, barrels, kegs or drums, previously used for the shipment of an inflammable, poisonous, or corrosive gas or liquid, must have their filling and vent holes properly closed. They should be loaded in open or stock cars when practicable. Labels are not required on such packages and cars should not be placarded, but lighted lanterns or other open-flame lights should be kept away.

Carboys previously used for the shipment of corrosive liquids, when presented to carriers for transportation in carload and less-than-carload shipments as "empty carboys," must be thoroughly drained. Whenever practicable they should not be loaded in cars containing valuable or perishable freight.

Empty bottles previously used for the shipment of nitric acid or nitric acid mixtures should be securely stoppered.

November Meeting, Deutsche Chemische Gesellschaft

The November meeting of the Deutsche Chemische Gesellschaft took place as usual in the lecture hall of the society building, the well-known Hoffmann House, Berlin, on Monday, Nov. 14. It was promptly opened at 7.15 p.m. by President C. Harries, the synthetic rubber chemist.

The deaths of the following members were announced: Dr. Fr. Stockhausen, of the Deutsche Gold & Silberscheidanstalt, in Frankfurt a-Main. Dr. Erich Kunheim, of Kunheim & Co., Niedenschönweide-Berlin.

Prof. Gabriel, of the Chemische Institut of the University of Berlin, who was present at the meeting, was officially congratulated on his seventieth birthday by the president in the name of the society.

The first paper was read by Dr. Hermann Mark, who offered his work on penta-arylethyls in defence of trivalent carbon. Prof. Schlenk, the present head of the Chemische Institut of the University of Berlin and successor to the famous Emil Fischer, helped to support the theory, which was first announced in 1900 by the American chemist Gomborg, that carbon, although usually tetravalent, can also exist in a trivalent state. All compounds with trivalent carbon are very unstable and highly colored. While in the past only the tri-arylmethyls were known, W. Schlenk and the speaker succeeded in producing the homologs of penta-arylethyl. Hereby a new and interesting proof of the existence of trivalent carbon was brought to light. An interesting debate followed between the president and Dr. Mark.

The second paper was read by Dr. Hans Enders, on "The Effect of NO on Sodiumalkyls." This interesting substance NO, in which nitrogen must be considered bivalent, acts upon metallo-organic compounds in two stages. Through this reaction, addition products are formed which are of special interest, as they can be considered as substitution products of hyponitrous acid $\text{HN}_2\text{O}_2\text{R}$. W. Schlenk and the speaker succeeded in isolating three different reaction products, whereby three isomers were secured. These three isomers were demanded by the theory of structural valence and the experimental proof of their existence reinforces anew the stereochemistry of nitrogen. In the discussion which followed Prof. P. Jakobson, the author of the well-known "Lehrbuch der organischen Chemie," the president and the speaker took active part.

The third paper was delivered by Dr. E. Tiede on "Phosphorescent Magnesium Sulphide." Up to now the only sulphides of the alkaline earths which served in the production of luminous paints were those Ca, Sr and Ba. The speaker has now also succeeded in producing pure magnesium sulphide through the use of ingeniously devised apparatus and the exercise of extraordinary experimental care, and he has shown that this alkaline earth sulphide is very well adapted to the production of phosphorescent materials. These new phosphorescent substances are easily excited by ultraviolet light and they shine particularly long and brightly.

The three lectures were well illustrated with lantern slides and with experimental proofs and demonstrations. The latter could be performed to great advantage on the excellently equipped lecture table of the Hoffmann House. The demonstrations of the many variously excited phosphorescent materials by the last speaker met with most enthusiastic applause.

Bibliography on Refractories

The Refractory Division of the American Ceramic Society has issued a new bulletin in the form of a bibliography of magnesite and dolomite refractories. Organizing Secretary Ross Purdy, Columbus, Ohio, has collaborated with A. S. Greaves-Walker, chairman of the division.

This is but the first of the bibliographies to be issued by the society. The Refractory Division will shortly issue other bulletins on chromium, sillimanite, alumina, spinel, silicon carbide, zirconia, carbon, clay and special refractories including nitrides and oxides. The U. S. Bureau of Mines, in Columbus, is collaborating in the preparation.

Spread of War Gases Subject to Control

In view of recently published statements that gas should be outlawed as a weapon of warfare because it would drift away from the actual scene of conflict and endanger civilian communities at a distance from the battlefield, General Amos A. Fries, the head of the Chemical Warfare Service, has authorized the following statement:

Chemical warfare gases can be confined in war to the fighting forces practically to the same extent that the action of high explosives, shells and bombs can be confined. There is a widespread feeling that even a small quantity of gas loosened in a territory is dangerous for long distances. This is absolutely incorrect. The most powerful gases of today volatilize so slowly that their effects will be felt only a few hundred yards from where they are dropped.

The idea that gases would be dangerous to surrounding populations for long distances arose from the early cloud gas attacks. To produce a cloud that would drift, say, 6 miles, would require 20 lb. or more of liquid gas per foot of front (or about 53 tons per mile) 2 miles or more in extent. Such concentrations will never be attempted except in the face of the enemy where the chances of inflicting heavy losses among his soldiers are worthy of the attempt.

The use of gases against crossroads, railroad centers, camps and the like would be of the mustard gas variety, due to the lasting qualities of those gases. Thus a bombardment with shells every 2 to 5 days would make the place dangerous for every man working in the area bombarded unless continuously protected by masks and gasproof clothing. The danger area, however, would extend but very little beyond the immediate area at any time, and hence would affect the immediate area and that area only.

American Foundrymen's Association to Meet in Cleveland

The city of Cleveland has been selected as the place of the next convention and exhibit of the American Foundrymen's Association, to be held during the week of April 24, 1922. The association headquarters and exhibits will be in the new Cleveland Public Hall, at Lakeside Ave. and East Ninth St., which is rapidly nearing completion. The Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers has announced that it will hold joint convention with the Foundrymen, as has been the custom in years past.

Of the cities considered, Cleveland is most centrally located for the membership, for the foundry industry and for the manufacturers of foundry equipment and supplies, who make annual exhibits, and its selection will conserve traveling and freight expense.

Following an interval of 18 months the next meeting promises to be of unusual interest and profit. The papers committee advises that manuscript copies are being received and that the first set of preprints of papers to be presented at the convention will be mailed out in January.

There never was a period when economy in production counted for so much as now. At the coming exhibit will be displayed all the latest improvements and inventions in foundry equipment.

Synthetic Camphor Factory May Resume Operations

Plans for the resumption of operations in the synthetic camphor factory of E. I. du Pont de Nemours & Co., Inc., at Deepwater Point, N. J., have been under discussion recently by large consumers of this product and officials of the du Pont company. The Deepwater plant has a capacity large enough to meet the requirements of the pyroxylin plastic manufacturers of the United States. These manufacturers were represented at the conference by N. M. Clark, vice-president of the Celluloid Company; H. R. Bemis, treasurer of the Fiberloid Corporation, and B. W. Doyle, treasurer of the Viscoloid Company.

Fire Caused by Sodium Peroxide

The analytical laboratory of the Central Scientific Co. of Chicago was recently badly damaged by fire started by a hundred pounds of sodium peroxide.

Plan to Avoid Duplication in Collecting Metal Statistics

The metal producers are having their interests made a matter of special consideration in connection with the biennial census of manufactures. Secretary of Commerce Hoover and Secretary of the Interior Fall have instructed Eugene F. Hartley, chief statistician of manufactures, and Dr. George Otis Smith, director of the U. S. Geological Survey, to recommend a plan to obviate duplication of government effort and to prevent unnecessary burdens on smelters and other sources of information required for the compilation of the statistics. The proposal which probably will be recommended to the two secretaries is that the Geological Survey, by reason of its constant touch with the mineral industry, act as the agent of the Bureau of the Census every two years and collect the special data desired at the time the figures of annual production are collected for the Survey's own use. It is the expressed desire of both Secretaries Fall and Hoover, each of whom knows the mining business from the inside, to make as few demands upon the accounting offices of the mining companies as is possible.

River Terminals Needed for Steel Shipments Into Cincinnati

Recent shipments of iron and steel from Pittsburgh and various cities along the Ohio River which have the necessary terminals have caused much comment among local business men, the products carried on these trips not being available to Cincinnati because of the difficulty of transferring them from barges to trucks or other vehicles. With proper terminal facilities much business that now goes to other cities would come to Cincinnati and at the same time local consumers would get the benefit of the lower space rates offered by the waterway carriers.

Several plans for terminals have already been worked out by engineers, and it is expected that early action will be taken to build river terminals at some advantageous point on the river front to take care of the ever-increasing shipments of heavy bulk freight into the city. The Chamber of Commerce is active in promoting a concerted effort to this end among the business interests.

Fertilizer Manufacturers Organize

Fertilizer manufacturers in the Del-Mar-Via Peninsula district, Maryland, are organizing an association to include all such interests throughout this section, to be known as the Peninsula Fertilizer Manufacturers' Association. Details of the new organization were perfected at an informal meeting at Salisbury, Md., Nov. 28, at which William B. Tilghman of the William B. Tilghman Co., Salisbury, was elected temporary chairman; E. Benson Dennis, of L. E. P. Dennis & Co., Crisfield, Md., vice-chairman; and William E. Valliant, Valliant Fertilizer Co., Georgetown, Del., temporary secretary. A meeting will be held soon to effect a permanent organization. Those represented in the new association include: William B. Tilghman Co. and the Farmers' & Planters' Co., both of Salisbury; L. E. P. Dennis & Co., Crisfield; Huston, Darby & Co., Seaford, Del.; Dorchester Fertilizer & Lime Co., Cambridge, Md.; W. H. Valliant & Bro., Bellevue, Md.; E. S. Valliant & Sons, Centerville, Md.; Worcester Fertilizer Co., Snow Hill, Md.; and the Valliant Fertilizer Co., Georgetown, Del.

Lehigh Valley Chemical Society Elects Officers

At a meeting of the Lehigh Valley Section of the American Chemical Society, held in Gayley Hall, Lafayette College, Easton, Pa., Dec. 1, the following officers were elected for the ensuing year: Chairman: P. R. Croll, New Jersey Zinc Co., Palmerton, Pa.; secretary and treasurer: H. A. Depew, New Jersey Zinc Co., Palmerton; first counselor: Dr. E. C. Bingham, Lafayette College; second counselor: Henry Wysor, Easton. The principal address of the evening was made by Dr. Charles L. Reese, research director, E. I. du Pont de Nemours & Co., Wilmington, Del., on the subject, "The Effect of Maintenance of the Dye Industry on Scientific Development in This Country."

Notes on Industrial Activities in Maine

Work on new construction for the Advance Bag & Paper Co. at Howland, Me., is progressing rapidly, about 200 men being employed at present. Crews of men have been working day and night on the coffer dam to enclose the site of the power house extension, which will increase the power production greatly. The new machine room will be 52 x 288 ft. New beater, Jordan and slusher rooms are also being built. Two 750-hp. boilers and a 400-ton overhead bunker are to be added to the power plant. The bag mill will be 150 x 65 ft., four stories high, and will house sixty modern bag machines. The new concrete dam, built last year in the Piscataquis River near its confluence with the Penobscot, will provide a supply of water for power for many years. The improvements will increase the paper production by about 48 tons daily and it is expected that there will be an output of over 2,000,000 bags daily.

The Bowdoin mill of the Pejepscot Paper Co., one of its six newsprint mills located at Topsham, Me., was shut down recently. This mill was formerly owned by the Cowles interests and it is believed that they are endeavoring to recover control of it.

Evidence on Dec. 1 indicates that the strike at the International Paper Co. mills at Livermore Falls is about at an end. The strike started May 1. Manager Murray states that eight of the machines at Livermore Falls are running. Eight machines of the same company at Palmer Falls and the sulphite mill at Chisholm are also in operation. The Webster mill of the International Paper Co., at Orono, Me., is now running on a normal production basis. The strikers have gradually returned or have been replaced.

The chemistry department of the University of Maine and the Maine Section of the American Chemical Society, under the direction of Dr. C. A. Brautlecht, have been showing moving pictures of chemical and metallurgical industries weekly. The films are those furnished by the Bureau of Mines and some of the leading industrial corporations.

Renewed activity in the building trades is causing an interest in the slate quarries near Brownville, Me. L. F. Johnson is temporary chairman of the newly organized board of trade of that town. Various concerns are investigating both the large masses of high-quality unquarried slate and the hills of accumulated waste near each quarry. The waste at practically all quarries will undoubtedly soon be crushed, screened and shipped to roofing paper mills as surfacing material and as filler in other industries. The Monson Slate Products Co., a Massachusetts corporation, has purchased one of the Blanchard quarries and is preparing to use some of this slate, after grinding, for coating asphalt shingles. Blanchard, Brownville and Monson quarries are being watched closely by parties interested in slate. The Monson Slate Products Co. has erected buildings for grinding and sieving waste slate.

Proposed Spanish Tax on the Export of Pyrites

The Huelva mine owners are beginning to protest against the proposed export duty of eight pesetas per ton on pyrites. They say that this duty will mean the ruin of the industry. The defenders of the future régime reply that the restrictions on exports will lead to the establishment in Spain of factories using this product, from which superphosphates, refined copper and sulphuric acid could be obtained.

Chemistry Building at University of Mississippi

The State Bond Improvement Commission, Jackson, Miss., has approved an award of contract to the Doullut & Williams Co., Hibernia Bldg., New Orleans, La., for the erection of a new fireproof chemistry building at the University of Mississippi, Oxford, to cost about \$160,000. Theodore C. Link, Director of Public Works, is in charge.

Colorado Clays Exploited

The U. S. Bureau of Standards will shortly analyze samples from clay deposits found in Grand Valley, Col. The local chambers of commerce at Grand Junction and Fruita are hoping to locate clays suitable for the making of brick, pottery and tiling.

Personal

R. L. AGASSIZ, Boston, Mass., has been elected president of the recently organized Copper and Brass Research Association.

WILLIAM T. ASHLEY has resigned as vice-president and general manager of the Hawk Nut Butter Co., Newark, N. J., to devote his time to the exploitation of his patents on a new process of margarine manufacture.

Dr. H. E. BARNARD, director of the American Institute of Baking, has moved his office from Minneapolis, Minn., to the new Institute home, 1135 Fullerton Ave., Chicago, Ill.

Prof. MARSTON T. BOGART, of Columbia University, addressed the Civic Club at Cleveland, Ohio, on Dec. 3, in defense of the proposed selective embargo on dyes. Dr. Bogart's address was in reply to one of the previous week, before the same audience, by a member of the editorial staff of *The Nation*, who attacked the embargo on the ground that it would foster monopoly.

WILLIAM M. BURTON, of the Standard Oil Co. of Indiana, will receive the Perkin Medal at the meeting of the Society of Chemical Industry at the Chemists' Club, New York, Jan. 13, 1922.

L. E. CALKINS, formerly superintendent of the Minneapolis plant of The Barrett Co., and F. SCHILLING, formerly superintendent of the St. Louis plant, are now members of the Chicago plant organization.

Dr. J. CAVALIER, recteur of the University of Toulouse, spoke before the Bureau of Standards scientific staff on Dec. 16 on the subject "Les Industries Chimiques en France pendant la Guerre."

FULLER CLARKSON left the Fixed Nitrogen Research Laboratory on Dec. 1 to become associated with the Procter & Gamble Co. He will study plant problems.

W. H. EISENMAN, national secretary of the American Society for Steel Treating, spoke before the Charleston, W. Va., chapter of the society on "Heat-Treating—Its Past, Present and Future."

H. S. GALE sailed on Dec. 13 for Colombia, where he will be engaged for three months in an oil investigation for an American company.

H. A. HAUPTLI, superintendent of Sears, Roebuck & Co.'s wallpaper mill, has just returned from an extended business trip through several European countries.

H. F. HERRICK, formerly of the National Aniline & Chemical Co., Buffalo, N. Y., has accepted a position as chemist with the American Aniline Products Co., Lock Haven, Conn.

HENRY JOSEPH, who received the degree of chemical engineer last June from Columbia University, has taken up work with the Consolidated Gas Co., as engineering assistant to Mr. Lunn, chief chemist.

Dr. ROBERT S. LANDAUER has accepted the position of research physicist with the Standard X-Ray Co. of Chicago.

W. LEE LEWIS, chemistry director at Northwestern University, is furnishing a new tear-gas bomb to the Chicago Police Department for combating dangerous criminals. It was used as an effective threat in the recent stockyard workers' strike in Chicago.

EDWARD S. LIEBSCHER has resigned as research chemist with the American Lead Pencil Co., Hoboken, N. J., and is now associated with the Far East Products Co., Inc., Brooklyn, N. Y. as president and chemical director.

Prof. A. S. LOEVENHART of the University of Wisconsin spoke on Nov. 17 on "The Relation Between Chemical Structure and Pharmacological Action." He also spoke at Northwestern University.

Prof. CHARLES MOUREU, of the College of France, president of the International Union of Pure and Applied Chemistry, and Prof. A. MAYER, of the University of Strasbourg, the two French chemical advisers at the Limitation of Arms Conference, spoke briefly before the Washington Section of the American Chemical Society on Dec. 8. They presented greetings of French chemists and spoke most encourag-

ingly of their interest in the international relations within the science.

A. PACYNA, formerly control chemist of production at the Chicago plant of The Barrett Co., is now a member of that company's research staff at Shadyside, N. J.

DON STEVENS, formerly with the technical division of the Goodyear Tire & Rubber Co., has accepted the managership of the Okonite Co., Passaic, N. J., manufacturer of insulated cable.

Prof. A. L. TATUM, of the department of pharmacology, University of Chicago, spoke to the Kent Chemical Society of the university on Nov. 10, on "The Equilibrium Between Stored and Circulatory Sugar in the Animal Organism."

MAURICE C. WALSH, who received the degree of chemical engineer from Columbia University last June, is now located at Mellon Institute, Pittsburgh. His work is in connection with the newer developments which are extending the uses of container board for packing cases.

Obituary

ARTHUR H. GALLUN, of A. F. Gallun & Sons, Milwaukee, died on Nov. 9, 1921, from an attack of pneumonia. He was associated with the leather industry all his life and worked constantly for a wider appreciation of the value of fundamental chemical research in this field.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Dec. 19, 1921.

The general activity of the chemical market during the period under review has shown that business so far is better than in November, but there still remains a pronounced tendency of quietness, owing to the holiday season and the inventory period. It is commonly known that these two influences always work against any temporary activity. Contract business for deliveries to begin after the first of the year is progressing well under adverse conditions and with every indication that January business will be far ahead of recent months. A great deal of readjustment has been going on at chemical plants and it is asserted that prices of many items have been revised to meet the law of supply and demand. Export conditions are gradually improving, and this is fully reflected in the number of inquiries reaching the market from Italy, South American countries and the Orient. The recent rise in foreign exchange, together with efforts now on foot to stabilize money, will go a long way toward stimulating our foreign trade. Prices in second hands show a decided weakness, but producers seem to be firmer in their views. Additional sales of contracts went through in solid caustic soda and soda ash, but spot trading in these commodities remained quiet, with occasional sales noted for export. Prices on spot were a trifle easier owing to the limited extent of inquiries and keener competition existing among second hands. Caustic potash looked slightly weaker. Bichromate of soda held on at former levels, with sales of a small nature from regular consuming channels. Anhydrous ammonia was reduced 1c per lb. by manufacturers after nearly an entire year at the former quotation. Oxalic acid is holding steady, with former prices held by leading sellers. Imported bromides are being offered on spot at prices materially lower than those named by domestic producers. Cream of tartar showed a little more strength and the market closed slightly higher. Makers of cyanide of soda are very firm in their ideas before the announcement of contract prices. Arsenic is quoted lower. Prussiate of soda was practically the only item that furnished excitement in the otherwise quiet market. The reduced spot supplies and the advanced foreign

exchange rates and an active inquiry from the consuming industries all had a tendency to shoot prices upward and the market closed in an exceedingly firm position.

CHEMICALS

Dealers offered solid *caustic soda* at \$3.80@\$3.85 per 100 lb. on spot and quoted \$3.90 f.a.s. The strength in foreign exchange is bringing out more inquiry for export and although sales could not be termed plentiful, moderate orders were reported to Europe, South America and Japan. Producers report sales at \$2.75 per 100 lb. and upward for forward shipment, basis 60 per cent, f.o.b. works. There was a slightly firmer feeling noted in *nitrite of soda* on spot. Some dealers were still quoting former figures ranging from 6½@7c per lb. The inquiry is not showing any pronounced activity and consumers are merely buying actual necessities, which in most cases consist of small quantities. The continual absence of any important orders for additional quantities of caustic potash, 88-92 per cent, has caused a rather easy undertone. Imported material is offered at 5½@5¾c per lb. and it is admitted in some directions that a shade under this figure might be accepted on firm business. Forward shipments are quoted at \$5.35@\$5.40 per 100 lb. Quiet trading featured the market on *bichromate of soda* and prices have shown no tendency to advance. Sales are reported at 7½@8c. per lb., with most transactions going through at the lower figure. Contract quotations were held by leading interests at 7¾c per lb. Offerings were not too plentiful, but seemed to be sufficient to meet the current extent of inquiries. *Prussiate of soda* stood alone as the feature of the week's activities. Supplies of imported material have remained in a few scattered hands and with the strength in money rates and the sold up condition of domestic manufacturers, prices on spot were sharply advanced. Sales were reported toward the close of the week as high as 15½c. per lb., with the majority of sellers asking 15¾@16c per lb. for the remaining odd lots. Buyers have not responded as quickly as the rise in prices, but those in need of supplies have to purchase at the present market quotations. Domestic *bleaching powder* is holding firm on the basis of \$2.25 per 100 lb. for large containers, f.o.b. works, and at \$2.50 per 100 lb. for small drums. Spot offerings of large drums are limited and the market appears quite firm at 2½@2¾c per lb. Imported bleach is quoted at \$2.20 per 100 lb. ex-dock, with only scattered lots obtainable. Dealers offered spot *strontium nitrate* at 11@12c. per lb., depending upon the quantity. Some small-lot sales have been reported, but business in this chemical has shown very little activity. Imported U.S.P. *permanganate of potash* is offered as low as 15½c. per lb., against a manufacturers' price of 22c. per lb. Producers of *cyanide of soda* are firmer in their views. The 96-98 per cent grade is quoted at 30c per lb., although a slightly lower figure could be done on round-lot business. Leading factors in *arsenic* are quoting various prices on spot. Resale merchants want 5½c. per lb. and makers name 6c. per lb. as their lowest.

GENERAL CHEMICALS

CHICAGO, Dec. 16, 1921.

Quieter conditions prevailed in the general chemical market during the past two weeks. This state of affairs is nothing unusual at this time of the year and a pickup can scarcely be expected until after New Year's. There is some tendency on the part of dealers to shade prices on account of the approaching inventory season, but low prices do not appear to tempt the buyer at this time. One large firm has given its salesmen a two weeks' vacation starting on the 19th. This firm reports that it is useless to send out salesmen, as buyers are practically out of the market and will stay out until their inventories are cleared up. All factors seem optimistic over the prospects for next year and expect to enjoy a good volume.

GENERAL CHEMICALS

The situation on alkalis lacks new developments and the spot market is quiet. Ground *caustic soda*, 76 per cent, is quoted at \$4.75 per 100 lb. and the solid at \$4.10@\$4.25. *Soda ash* is moving only in small quantities and is unchanged at \$2.60 per 100 lb. in cooperage. *Caustic potash*

is quiet and supplies are available in the spot market at 6½@6¾c. per lb. *Potash alum* is firm and supplies are light. The lump is quoted at 5½@6c. per lb. and the powdered at 6½@7c. The demand for *ammonium carbonate* is limited and small spot stocks are offered at 9@10c. per lb. *Bleach* is moving in a routine way at 3@3¼c. per lb. for large drums. *Carbon bisulphide* is firm and lacks quotable change at 7@7½c. per lb. *Carbon tetrachloride* is in moderate demand and quotations are firm at 10½@11c. per lb. *Glycerine* was advanced again by refiners and is very firm at 15½c. per lb. for c.p. material in drums. *Epsom salts* are quiet, with supplies of the U.S.P. material offered at 2¾c. per lb. Single *nickel salts* are quoted lower by first hands, the new level being 11c. per lb.

Potassium bichromate is rather slow and supplies are available at 13@13½c. per lb. *Soda bichromate* is scarce, and 8½c. was the best offer noted. *Potassium chlorate* is firm and scarce. The small stocks on spot are quoted at 8¾@10c. for crystals and 8½@9c. for powdered. *Red prussiate of potash* has shown a firmer tendency and is offered at 28½@30c. per lb., according to seller and quantity. *Yellow prussiate* is also firm at 24@25c. per lb. *Sal ammoniac*, while very firm and scarce, is unchanged at 8@8½c. per lb. for the white granulated. *Bicarbonate of soda* is moving in a routine way at \$2.60 per 100 lb. *Sodium fluoride* is rather quiet at 11@12c. per lb. *Hyposulphite of soda* is not moving very well, although the photographic trade continues to purchase small lots. *Pea crystals* are unchanged at \$4.05 per 100 lb. in barrels.

The acid business is dull and prices are unchanged. *Acetic acid* is moving only in small lots and is quoted at 2¾c. per lb. for 28 per cent in barrels. *Glacial acetic acid* business is practically at a standstill, but prices remain the same. *Oxalic acid* is attracting but little attention and supplies are offered at 15@16c. per lb. *Phosphoric acid* is very quiet and the sirupy, 85 per cent, is quoted at 19@21c. per lb. The heavy acids are unchanged as to price and plentiful. *Sulphuric acid* is quoted in tank cars at the works at \$18@\$20 per ton.

PHARMACEUTICALS

There is a fair volume of business reported from this branch of the trade and practically all prices are firm. *Bismuth* metal advanced again to \$1.80 per lb. in 500-lb. lots. No announcement of a change in bismuth preparations came from manufacturers, but it is scarcely possible to maintain the present level in the face of the last three advances on the metal. *Mercurials* are very firm and are said to be moving in a satisfactory manner. Like bismuth, mercury metal has advanced rapidly of late with no corresponding advance in the preparations. *Iodine* and all iodides were advanced 30c. per lb. by manufacturers this week. This makes the new level for *potassium iodide* \$2.90 per lb. and for *iodine* \$3.80. Business on iodides was reported as very good by both first hands and dealers.

VEGETABLE OILS

There is only a routine demand for *linseed oil* and inquiries were reported as light. The boiled oil is quoted today at 69c. per gal. in 5-drum lots and the raw at 67c.

NAVAL STORES

The naval stores market is a rather quiet affair and only small business was reported. *Spirits of turpentine* was offered today at 80c. per gal. in 5-drum lots, but the movement was slow. *Rosins* are slightly lower in price.

The Iron and Steel Market

PITTSBURGH, Dec. 16, 1921.

Under date of Dec. 15 the National Tube Co., issued new price lists, increasing discounts on standard steel pipe, except ½-in., 2½ points or about \$5 per net ton, also on O.D. pipe, while oil country goods, which are quoted in net prices, were reduced approximately the same amount per ton. Line pipe discounts were increased 3 points. The action of the Steel Corporation subsidiary was taken on account of continued shading by independents, the shading beginning very shortly after the reduced prices of Sept. 16 were issued. Line pipe is usually shaded on large orders, but of late the shading has been very deep, and there have been

a few cases of deep shading in oil country goods. In standard steel pipe the shading was shallow, but had become almost universal. Possibly the shading would have been deeper had not the independents quite generally had price guarantees outstanding, providing a concession on all carload shipments made within 60 days of a general reduction. The shading was generally an extra 5 per cent instead of the 2½ per cent the independents frequently give from the leading interest's prices. Thus the official reduction goes quite beyond the shading.

The most interesting feature of the decline in tubular goods is the test it furnishes to the general rule that finished steel prices are practically stationary now because demand is light and orders are small individually, too small to provoke very active price competition. In tubular goods the demand has been heavier than demand for any other important finished steel product and has represented 70 or 80 per cent of the pipe mill capacity, conservatively estimated. Other steel products show no noteworthy price change in the past week or indeed for several weeks.

Shading in tin plate has spread somewhat and the market is quotable now at \$4.65@\$.4.75 against \$.4.75 flat formerly quoted. Sheets, on the other hand, are the most rigidly held of any finished steel product, buyers finding it quite impossible to shade 3c on black or 4c on galvanized. The condition is the more remarkable on account of the recent great irregularities in sheet prices.

Bars, shapes and plates remain quotable at a range of 1.50@1.60c., but the lower price is more common. Wire products in general are at prices ruling before the advance of Sept. 12, which proves to have been largely on paper, and there is occasional shading at that.

PITTSBURGH BASING

The long-established custom of Pittsburgh basing, or "Pittsburgh plus," the practice complained of months ago before the Federal Trade Commission and on which hearings are to begin next month, is less and less in evidence. The departure is of course due chiefly to the strongly competitive conditions existing when demand is far below productive capacity, but is no doubt encouraged by the high freight rates now ruling. The Pittsburgh basis obtains in sheets and tin plates, but in practically all other commodities there are some cases of departures, by Eastern, Buffalo, Southern and Western mills. Usually the Pittsburgh and valley mills do not meet the special prices thus made, but occasionally they do, thus accepting lower prices f.o.b. their mills than they would receive when selling in nearby territory.

PRODUCTION

Production is fairly well maintained by the Steel Corporation, while independent mill operations have decreased considerably since the high point early in November, when ingot output was at the rate of about 25,000,000 tons per annum, or 48 per cent of capacity, while the rate now is about 21,000,000 tons or 40 per cent. Unless there is a phenomenal increase in steel demand in the not distant future the present practice of speaking of steel production in terms of percentage of capacity will yield to a style of referring to production in terms of actual tons, the estimated capacity coming to have only theoretical interest. The tonnage concept is much more cheering. Thus the recent rate of about 25,000,000 tons was equal to the production in 1910, when the mills operated substantially at their capacity.

PIG IRON

Foundry pig iron, quotable for weeks past at \$20.50 valley, the price gradually becoming nominal, has sold in a few small lots at \$19.50, making a more substantial quotation and putting foundry between bessemer, at \$20, and basic, at \$19, a position that seems more natural. The whole pig iron market remains decidedly stagnant and consumptive requirements are evidently decreased, for a mere "waiting policy" on the part of buyers would not account for the long-continued apathy.

Connellsville furnace coke for spot shipment is quotable nominally at \$3 per net ton f.o.b. ovens, a price that would probably be shaded if there were any important inquiry. Spot foundry ranges from \$3.75 to \$4.50 according to brand.

Alpha-naphthol, crude.....	lb.	\$1.10 - \$1.15
Alpha-naphthol, refined.....	lb.	1.25 - 1.30
Alpha-naphthylamine.....	lb.	.30 - .32
Aniline oil, drums extra.....	lb.	.17 - .19
Aniline salts.....	lb.	.24 - .26
Anthracene, 80% in drums (100 lb.).....	lb.	.75 - 1.00
Benzaldehyde U.S.P.....	lb.	1.35 - 1.45
Benzidine, base.....	lb.	.90 - 1.00
Benzidine sulphate.....	lb.	.75 - .85
Benzoic acid, U.S.P.....	lb.	.60 - .65
Benzoate of soda, U.S.P.....	lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.).....	gal.	.27 - .32
Benzene, 90%, in drums (100 gal.).....	gal.	.25 - .28
Benzyl chloride, 95-97%, refined.....	lb.	.25 - .27
Benzyl chloride, tech.....	lb.	.20 - .23
Beta-naphthol benzoate.....	lb.	3.75 - 4.00
Beta-naphthol, sublimed.....	lb.	.70 - .75
Beta-naphthol, tech.....	lb.	.30 - .34
Beta-naphthylamine, sublimed.....	lb.	1.75 - 1.85
Cresol, U. S. P., in drums (100 lb.).....	lb.	.15 - .16
Ortho-cresol, in drums (100 lb.).....	lb.	.24 - .26
Cresylic acid, 7-9% straw color, in drums.....	gal.	.70 - .80
Cresylic acid, 35-97%, dark, in drums.....	gal.	.65 - .70
Cresylic acid, 50%, first quality, drums.....	gal.	.45 - .50
Dichlorobenzene.....	lb.	.06 - .09
Diethylaniline.....	lb.	.95 - 1.10
Dimethylaniline.....	lb.	.40 - .45
Dinitrobenzene.....	lb.	.23 - .27
Dinitrochlorobenzene.....	lb.	.20 - .25
Dinitronaphthalene.....	lb.	.30 - .35
Dinitrophenol.....	lb.	.35 - .40
Dinitrotoluene.....	lb.	.25 - .30
Dip oil, 25%, car lots, in drums.....	gal.	.30 - .35
Diphenylamine.....	lb.	.60 - .70
H-acid.....	lb.	1.00 - 1.10
Meta-phenylenediamine.....	lb.	1.10 - 1.15
Monochlorobenzene.....	lb.	.12 - .14
Monoethylaniline.....	lb.	1.65 - 1.70
Naphthalene crushed, in bbls.....	lb.	.07 - .08
Naphthalene, flake.....	lb.	.07 - .08
Naphthalene, balls.....	lb.	.08 - .09
Naphthionic acid, crude.....	lb.	.70 - .75
Nitrobenzene.....	lb.	.12 - .15
Nitro-naphthalene.....	lb.	.30 - .35
Nitro-toluene.....	lb.	.15 - .17
Ortho-amidophenol.....	lb.	3.00 - 3.10
Ortho-dichlor-benzene.....	lb.	.15 - .20
Ortho-nitro-phenol.....	lb.	.77 - .80
Ortho-nitro-toluene.....	lb.	.15 - .20
Ortho-toluidine.....	lb.	.20 - .25
Para-amidophenol, base.....	lb.	1.40 - 1.45
Para-amidophenol, HCl.....	lb.	1.70 - 1.80
Para-dichlorobenzene.....	lb.	.12 - .15
Paranitroaniline.....	lb.	.77 - .80
Para-nitrotoluene.....	lb.	.80 - .85
Para-phenylenediamine.....	lb.	1.70 - 1.75
Para-toluidine.....	lb.	1.25 - 1.40
Phthalic anhydride.....	lb.	.37 - .40

Phenol, U. S. P., drums.....	lb.	.11 - .15
Pyridine.....	gal.	2.00 - 3.50
Resorcinol, technical.....	lb.	1.50 - 1.60
Resorcinol, pure.....	lb.	2.00 - 2.25
Salicylic acid, tech., in bbls.....	lb.	.20 - .21
Salicylic acid, U. S. P.....	lb.	.22 - .23
Salol.....	lb.	.70 - .72
Solvent naphtha, water-white, in drums, 100 gal.....	gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal.	.14 - .16
Sulphanilic acid, crude.....	lb.	.27 - .30
Tolidine.....	lb.	1.30 - 1.35
Toluidine, mixed.....	lb.	.43 - .45
Toluene, in tank cars.....	gal.	.25 - .28
Toluene, in drums.....	gal.	.28 - .31
Xylidines, drums, 100 gal.....	lb.	.40 - .45
Xylene, pure, in drums.....	gal.	.40 - .45
Xylene, pure, in tank cars.....	gal.	.45 - .45
Xylene, commercial, in drums, 100 gal.....	gal.	.33 - .35
Xylene, commercial, in tank cars.....	gal.	.30 - .30

Waxes

Prices based on original packages in large quantities.

Bayberry Wax.....	lb.	\$0.21 - \$0.22
Beeswax, refined, dark.....	lb.	.24 - .25
Beeswax, refined, light.....	lb.	.28 - .30
Beeswax, white pure.....	lb.	.34 - .38
Cardellina wax.....	lb.	.24 - .24
Carnauba, No. 1.....	lb.	.45 - .46
Carnauba, No. 2, North Country.....	lb.	.23 - .24
Carnauba, No. 3, North Country.....	lb.	.13 - .14
Japan.....	lb.	.21 - .21
Montan, crude.....	lb.	.04 - .04
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.04 - .04
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	.03 - .03
Paraffine waxes, refined, 118-120 m.p.....	lb.	.03 - .04
Paraffine waxes, refined, 125 m.p.....	lb.	.04 - .04
Paraffine waxes, refined, 128-130 m.p.....	lb.	.04 - .04
Paraffine waxes, refined, 133-135 m.p.....	lb.	.05 - .05
Paraffine waxes, refined, 135-137 m.p.....	lb.	.05 - .05
Stearic acid, single pressed.....	lb.	.09 - .09
Stearic acid, double pressed.....	lb.	.09 - .09
Stearic acid, triple pressed.....	lb.	.10 - .10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.....	280 lb.	\$5.30 - 5.35
Rosin E-I.....	280 lb.	5.40 - 5.50
Rosin K-N.....	280 lb.	6.05 - 6.75
Rosin W. G. W. W.....	280 lb.	7.00 - 7.25
Wood rosin, bbl.....	280 lb.	6.25 - .
Spirits of turpentine.....	gal.	.82 - .
Wood turpentine, steam dist.....	gal.	.80 - .
Wood turpentine, dest. dist.....	gal.	.78 - .
Pine tar pitch, bbl.....	200 lb.	. - 6.00
Tar, kiln burned, bbl. (500 lb.).....	bbl.	. - 9.50
Retort tar, bbl.....	500 lb.	. - 9.50
Rosin oil, first run.....	gal.	.36 - .
Rosin oil, second run.....	gal.	.39 - .
Rosin oil, third run.....	gal.	.46 - .
Pine oil, steam dist., sp.gr. 0.930-0.940.....	gal.	\$1.90 - .
Pine oil, pure, dest. dist.....	gal.	1.50 - .
Pine tar oil, ref., sp.gr. 1.025-1.035.....	gal.	.46 - .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.35 - .
Pine tar oil, double ref., sp.gr. 0.965-0.990.....	gal.	.75 - .
Pine tar, ref., thin, sp.gr. 1.080-1.960.....	gal.	.35 - .
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	1.25 - .
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990.....	gal.	.35 - .
Pinewood creosote, ref.....	gal.	.52 - .

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.37 - .
70-72 deg., steel bbls. (85 lb.).....	gal.	.35 - .
68-70 deg., steel bbls. (85 lb.).....	gal.	.34 - .
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.23 - .

Fertilizers

Ammonium sulphate, bulk and d. bags.....	100 lb.	\$2.30 - 2.90
Blood, dried, f.o.b., N. Y.....	unit	4.00 - .
Bone, 3 and 50, ground, raw.....	ton	30.00 - 32.00
Fish scrap, dom., dried, f.o.b. works.....	unit	2.90 - 3.00
Nitrate soda.....	100 lb.	2.30 - 2.35
Tankage, high grade, f.o.b. Chicago.....	unit	2.75 - 3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c.....	ton	4.50 - 6.50
Tennessee, 78-80 p.c.....	ton	8.50 - 9.00
Potassium muriate, 80 p.c.....	ton	34.00 - 35.00
Potassium sulphate.....	unit	.90 - 1.00

Crude Rubber

Para-Upriver fine.....	lb.	\$0.23 - .23
Upriver coarse.....	lb.	.13 - .14
Upriver cauchoball.....	lb.	.13 - .13
Plantation—First latex crepe.....	lb.	.18 - .18
Ribbed smoked sheets.....	lb.	.18 - .19
Brown crepe, thin, clean.....	lb.	.15 - .
Amber crepe No. 1.....	lb.	.17 - .

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls.....	lb.	\$0.10 - \$0.10
Castor oil, AA, in bbls.....	lb.	.11 - .12
China wood oil, in bbls. (f.o.b. Pac. coast).....	lb.	.13 - .13
Cocoonut oil, Ceylon grade, in bbls.....	lb.	.09 - .09
Cocoonut oil, Cochinchina grade, in bbls.....	lb.	.10 - .10
Corn oil, crude, in bbls.....	lb.	.08 - .08
Cottonseed oil, crude (f. o. b. mill).....	lb.	.07 - .07
Cottonseed oil, summer yellow.....	lb.	.08 - .09
Cottonseed oil, winter yellow.....	lb.	.09 - .09

Linseed oil, raw, ear lots (domestic).....	gal.	.67	—	.68
Linseed oil, raw, tank cars (domestic).....	gal.	.62	—	.63
Linseed oil, in 5-bbl lots (domestic).....	gal.	.70	—	.71
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palm, Lagos.....	lb.	.07 ³ / ₄	—	.08
Palm, Niger.....	lb.	.06 ¹ / ₂	—	.06 ¹ / ₂
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08 ¹ / ₄	—	.08 ¹ / ₄
Peanut oil, refined, in bbls.....	lb.	.11	—	.11 ¹ / ₄
Rapeseed oil, refined in bbls.....	gal.	.84	—	.85
Rapeseed oil, blown, in bbls.....	gal.	.88	—	.90
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.08 ³ / ₄	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07 ³ / ₄	—	

FISH

Light pressed menhaden.....	gal.	\$0.40	—	
Yellow bleached menhaden.....	gal.	.42	—	
White bleached menhaden.....	gal.	.45	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$23.00	—	23.50
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	15.00	—	17.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	6.00	—	7.00
Blanc fixe, dry.....	lb.	.04	—	.04 ¹ / ₂
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.15	—	.16
Chalk, Precipitated, domestic, extra light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04 ¹ / ₂
Chalk, Precipitated, domestic, heavy.....	lb.	.03 ¹ / ₂	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04 ¹ / ₂
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Ia.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.05 ¹ / ₂	—	.06 ¹ / ₂
Graphite, Ceylon chip.....	lb.	.04	—	.05
Graphite, high grade amorphous crude.....	lb.	.00 ³ / ₄	—	.02 ¹ / ₂
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr, f.o.b. N. Y.....	per ton	55.00	—	60.00
Magnesi.e, calcined.....	per ton	50.00	—	65.00
Pumice stone, imported.....	lb.	.03	—	.40
Pumice stone, domestic, lump.....	lb.	.05	—	.05 ¹ / ₂
Pumice stone, domestic, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1 ¹ / ₂ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.68	—	.70
Shellac, orange superfine.....	lb.	.78	—	.80
Shellac, A. C. garnet.....	lb.	.58	—	.60
Shellac, T. N.....	lb.	.68	—	.70
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.25	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	7.50	—	11.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$50.00		
Carborundum refractory brick, 9-in.	1,000	1250.00		
Chrome brick, f.o.b. Eastern shipping points.....	net ton	52- 55		
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30- 32		
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in ear lots, f.o.b. Eastern shipping points.....	net ton	33- 35		
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	35- 40		
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30- 35		
Magnesite brick, 9-in. straight.....	net ton	65- 70		
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77		
Magnesite brick, soaps and splits.....	net ton	98		
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	40- 42		
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	42- 45		
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35- 38		

Ferro-Alloys

All f.o.b. Works

Ferrocobalt-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, earlots.....	lb.	.12	—	
Ferrochrome, per lb. of Cr. contained, 4-6% carbon, earlots.....	lb.	.13	—	
Ferromanganese, 76-80% Mn, domestic.....	gross ton	58.00	—	60.00
Ferromanganese, 76-80% Mn, Foreign, C. I. F. Atlantic Seaport.....	gross ton	54.00	—	58.35
Spiegeleisen, 18-22% Mn.....	gross ton	25.00	—	27.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.25	—	
Ferrosilicon, 10-15%.....	gross ton	38.00	—	40.00
Ferrosilicon, 50%.....	gross ton	57.00	—	59.00
Ferrosilicon, 75%.....	gross ton	120.00	—	125.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.40	—	.45
Ferroumium, 35-50% of U, per lb. of U content.....	lb.	6.00	—	
Ferrovandium, 30-40% per lb. of contained V.....	lb.	4.25	—	4.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content.....	net ton	\$8.00	—	\$10.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	ton	22.00	—	23.00
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	ton	22.00	—	23.00
Coke, foundry, f.o.b. ovens.....	net ton	4.25	—	4.50
Coke, furnace, f.o.b. ovens.....	net ton	3.25	—	3.50
Fluorspar, gravel, f.o.b. mines, New Mexico.....	net ton	12.00	—	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	20.00	—	22.00
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01 ¹ / ₂	—	.01 ¹ / ₂
Manganese ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.23	—	.24
Manganese ore, chemical (MnO ₂).....	net ton	55.00	—	60.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.45	—	.50
Monazite, per unit of ThO ₂ , c.i.f. Atlantic seaport.....	unit	30.00	—	
Pyrites, Spanish, fines, c.i.f. Atlantic seaport.....	unit	.12	—	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport.....	unit	.13	—	.13
Pyrites, domestic, fines, f.o.b. mines, Ga.....	unit	.11	—	.12
Rutile, 95% TiO ₂ per lb. ore.....	lb.	.15	—	
Tungsten, scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	2.50	—	2.75
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.....	unit	2.75	—	3.00
Uranium ore (carnotite) per lb. of U ₃ O ₈	lb.	1.25	—	1.75
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.25	—	2.50
Vanadium pentoxide, 99%.....	lb.	12.00	—	14.00
Vanadium ore, per lb. of V ₂ O ₅ contained.....	lb.	1.00	—	
Zircon, washed, iron free, f.o.b. Pablo, Florida.....	lb.	.04 ¹ / ₂	—	.13

Non-Ferrous Metals

New York Markets

Cents per Lb.

Copper, electrolytic.....	13.75
Aluminum, 98 to 99 per cent.....	19.00
Antimony, wholesale lots, Chinese and Japanese.....	4.50
Nickel, ordinary (ingot).....	41.00
Nickel, electrolytic.....	44.00
Monel metal, shot and blocks.....	35.00
Monel metal, ingots.....	38.00
Monel metal, sheet bars.....	40.00
Tin, 5-ton lots, Straits.....	33.00
Lead, New York, spot.....	4.70
Lead, E. St. Louis, spot.....	4.35 @ 4.40
Zinc, spot, New York.....	5.25 @ 5.30
Zinc, spot, E. St. Louis.....	4.80 @ 4.85

OTHER METALS

Silver (commercial).....	oz.	\$0.65 ¹ / ₂
Cadmium.....	lb.	1.00-1.25
Bismuth (500 lb. lots).....	lb.	1.50 @ 1.55
Cobalt.....	lb.	3.00 @ 3.25
Magnesium (f.o.b. Philadelphia).....	lb.	1.25
Platinum.....	oz.	75.00-78.00
Iridium.....	oz.	150.00 @ 170.00
Palladium.....	oz.	55.00-60.00
Mercury.....	.75 lb.	48.00-49.00

FINISHED METAL PRODUCTS

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by 1/2 in. and larger, and plates 1/2 in. and heavier, from jobbers' warehouses in the cities named:

	New York	Cleveland	Chicago
Structural shapes.....	\$2.78	\$2.88	\$2.78
Soft steel bars.....	2.68	2.78	2.68
Soft steel bar shapes.....	2.68	2.78	2.68
Soft steel bands.....	3.28	3.48	3.28
Plates, 1/2 to 1 in. thick.....	2.78	2.88	2.78

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—A. B. Banks, Little Rock, and Burton B. Tuttle, Cincinnati, O., are organizing a new company for the operation of a plant for the manufacture of fertilizer, whitening and kindred products on property recently acquired at White Cliffs on the Little River, between Nashville and Ashdown, Ark. The site totals over 2,500 acres of land and was obtained for a consideration said to be about \$500,000. A chalk works will also be established in connection with the project. The new company will operate with a capital of \$1,000,000.

FORT SMITH—The Crystal Glass Co., Ninth and O Sts., is planning for the remodeling of its plant, with extensions and improvements estimated to cost about \$75,000. C. P. Zenor heads the company.

California

CHICO—The Shell Oil Co., 343 Sansome St., San Francisco, has plans under way for the construction of a new distributing plant on a 2-acre plot of ground, known as the Thompson property, Chico, estimated to cost about \$60,000, including equipment.

Colorado

GRAND JUNCTION—The Grand Junction Gas Co. plans an expenditure of \$25,000 for the enlargement of its plant. J. Stewart is general superintendent.

Connecticut

BRIDGEPORT—The D. & C. Oil Co., Lindley St., has completed plans for the erection of a new 1-story plant, 25 x 80 ft., on Colonial Ave., estimated to cost about \$25,000.

Indiana

MICHIGAN CITY—A 1-story foundry addition, with power plant, estimated to cost about \$500,000, including machinery, will be erected at the plant of the Haskell & Barker Car Co. Bids have been taken. Frank D. Chase, Inc., 545 North Michigan Ave., Chicago, Ill., is architect and engineer.

Kentucky

CORBIN—The Corbin Brick Co. is planning for extensions in its plant to increase the capacity from about 15,000 to 30,000 bricks per day. Two new kilns will be constructed, drier equipment and other apparatus installed. The company has recently increased its capital from \$50,000 to \$100,000 for expansion. Benn Goodwin is manager.

Louisiana

KENNER—The National Petroleum Co., Hibernia Bank Bldg., New Orleans, La., is planning for the erection of a new oil-refining plant in the vicinity of Kenner, La. P. A. Leslie is manager.

GRETNNA—The United States Flour Mills Co., 606 Common St., New Orleans, is perfecting plans for the erection of a new flour mill at Gretna, with initial capacity of about 6,000 bbl. of flour per day. An extensive laboratory will be established in connection with the works. W. L. O'Daniel is president.

ALEXANDRIA—The Alexandria Refining Co., recently organized, has construction under way on a new local oil refinery for the production of gasoline, kerosene and petroleum byproducts. It is proposed to have the plant ready for service at an early date. E. M. Talley is general manager.

Maryland

BALTIMORE—The Bethlehem Steel Co., Bethlehem, Pa., has preliminary plans under way for extensions and improvements in its local plant, estimated to cost close to \$50,000,000. The plans are being developed and will provide, it is said, for about twice the present output. The present plant, known as the Sparrow Point

Works, represents an investment of more than \$70,000,000.

BALTIMORE—The Central Chemical Co. has acquired the plant of the D. B. Marton Co., 1630 Clinton St., and will use the property for a new chemical manufacturing works. Possession will be taken at once.

BALTIMORE—The National Wall Paper Co., 1009 East Baltimore St., has had plans prepared for the erection of an addition, 40 x 100 ft., to its 3-story building at 706 East Baltimore St.

BALTIMORE—The new oil refinery now being constructed by the Standard Oil Co. is estimated to represent a total investment of \$7,000,000, and will rank as the second largest plant of its kind in the world. It will be placed in operation as soon as completed. The company will build a new tankage department at First Ave. and Fourteenth St., to cost about \$30,000.

Massachusetts

WALTHAM—The Elastoid Fiber Co., Norman and Marshall Sts., has construction under way on a new 1-story plant, 72 x 180 ft., in the vicinity of Pond St. It is expected to be ready for occupancy at an early date. A 1-story power house will also be constructed. The H. P. Cummings Construction Co., Ware, Mass., has the erection contract.

Michigan

BAY CITY—The Aetna Portland Cement Co., Union Trust Bldg., Detroit, has acquired property at Bay City, totaling about 30 acres, as a site for the erection of a large cement-manufacturing plant. Preliminary plans are under way for the first plant unit, designed in the form of an inverted U, with total area 375 x 900 ft. It will consist of a grinding department, 60 x 60 ft.; cooling department; 3 kilns; machine repair shop; coating department; and power plant. Docks and other transportation facilities will be constructed. The plant unit will have an initial minimum output of about 300 bbl. per day, and is estimated to cost close to \$750,000. It is proposed to commence erection early in the spring. The plant will be operated in conjunction with the present works of the company at Fenton, Mich. Franklin R. Robinson is president; and O. J. Lingeman, secretary.

Missouri

MARSTON—The East St. Louis Cotton Oil Co., is planning for the rebuilding of the portion of its local plant, recently destroyed by fire with loss of about \$30,000.

ST. LOUIS—The Red Spot Paint & Varnish Co., 1534 North Eighth St., is perfecting plans for the immediate remodeling and improving of the 3-story factory, 40 x 125 ft., recently acquired, for the establishment of a new plant for the manufacture of paints and varnishes for industrial and other service. P. C. Fryaser is general manager.

New Jersey

JERSEY CITY—The Ault & Wiborg Chemical Co., 432 New St., Cincinnati, O., manufacturer of printing inks, etc., has acquired the property of the Cockburn Corp., Monmouth and Twelfth Sts., Jersey City, including land and buildings, and will occupy the premises for a plant.

EAST ROCHESTER—The Merchants' Dispatch Transportation Co., has completed plans and will soon commence the erection of a 1-story addition to its steel-fabricating plant, 60 x 80 ft. L. F. West is head.

CUYLERVILLE—The Sterling Salt Co., 29 Broadway, New York, has awarded a contract to Dwight P. Robinson & Co., 126 East Forty-Sixth St., for the erection of a new building at Cuylerville.

Ohio

AKRON—The National Sulphur Co., 80 Maiden Lane, New York, has completed plans and will take bids at once for the construction of a new sulphur plant on Talmadge Road, Akron, to consist of four 1-story buildings, estimated to cost about

\$300,000, including machinery. C. S. Clark, 212 Ohio Bldg., Akron, is engineer.

AKRON—The Seiberling Rubber Co., recently organized under Delaware laws, is arranging for a stock issue of \$2,000,000, the proceeds to be used for general operations, expansion, etc. The company proposes to develop a capacity of about 5,000 automobile tires and 6,000 tubes daily at its two plants at New Castle, Pa., and Barberton, Ohio, the latter comprising the former works of the Portage Rubber Co., lately purchased. Cord tires, also, will be manufactured at the plants. F. A. Seiberling, formerly president of the Goodyear Tire & Rubber Co., is president; and C. W. Seiberling, vice-president.

Oklahoma

MUSKOGEE—The Muskogee Vitrified Brick Co. is planning for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about \$50,000, including equipment.

Pennsylvania

BRACKENBRIDGE—The Atlantic Bottling Co. has construction in progress for a new 2-story plant, 100 x 250 ft., estimated to cost about \$35,000. Allan & Kestner, Tarentum, Tarentum, Pa., are architects.

PITTSBURGH—The Neely Oil & Production Co., Pittsburgh, is planning for the establishment of a new oil-refining plant on a site in Allen County, Ky. It is said that work will be inaugurated at an early date.

DERRY—The Pittsburgh High Voltage Insulator Co., is considering tentative plans for the erection of an addition to its plant.

Tennessee

NASHVILLE—Mercer Reynolds, Chattanooga, Tenn., is perfecting plans for the organization of a new company, to construct and operate a plant at Nashville, where a site has been acquired. The new plant will manufacture paper products from cotton linters, under a special process. A specialty will be made of fine bond papers.

Texas

WACO—William Sacks, Tulsa, Okla., is planning for extensions and improvements in the local refinery of the Waco Refining Co., recently acquired. The present capacity of 5,000 bbl. per day will be increased. A new pipeline will be constructed from Mexia to Waco. The entire project is estimated to cost in excess of \$750,000, including equipment.

PORT ARTHUR—Fire, Dec. 5, destroyed a portion of the local oil refinery of the Texas Co., Dallas, Tex. The loss, official estimate of which has not been made, included high pressure stills and other equipment.

Virginia

RICHMOND—George Gibson, Richmond Trust Co. Bldg. Seventh and Main Sts., operating the Industrial Realty Corp., has awarded a contract to John T. Wilson & Co., Inc., Mutual Bldg., for the erection of a new 1-story and basement plant, 102 x 202 ft., at Seventh and Everett Sts., to be equipped for the manufacture of paper products. It is estimated to cost about \$75,000. Carneal & Johnston, Chamber of Commerce Bldg., are architects.

West Virginia

SALEM—The Salem Flint Glass Co., recently organized, will install considerable glass-manufacturing equipment in an existing building, for the manufacture of shades, globes and kindred glass specialties. R. F. Davis is president, and J. O. Burkhard, general manager.

WHEELING—The Wheeling Mold & Foundry Co. has extensive improvement work under way at its plant, including the remodeling of certain departments and equipment. The plant will be placed in operation, it is said, at an early date.

Wisconsin

GREEN BAY—The Fort Howard Paper Co. has active construction under way on a new 3-story paper mill, 100 x 120 ft., in the East Side section, estimated to cost about \$85,000. The plant will be occupied as soon as completed.

Ontario

LONDON—The Board of Education asks for bids on complete equipment for chemistry and physics laboratories for a new high school, estimated cost \$15,000. L. E. Carrothers is the engineer.

New Companies

THE WAXTWELL PAPER Co., Grand Rapids, Mich., has been incorporated with a capital of \$10,000, to manufacture waxed, plain and other papers. The incorporators are Archibald I. McCall, Grand Rapids; John F. Hastings, Jr., and George J. Putt, Kalamazoo, Mich.

THE AMERICAN ALUMINUM CASTING Co., Newark, N. J., has been incorporated with a capital of \$25,000, to manufacture aluminum and other metal castings. The incorporators are John Rohn, Frank T. Schmuhl and Henry Brucker, 324 Colt St., Newark.

THE METROPOLITAN POTTERY Co., Woodhaven, L. I., has been incorporated with a capital of \$50,000, to manufacture pottery products of various kinds. The incorporators are A. and H. Ratner, and N. McCoy. The company is represented by W. Augenmeyer, Woodhaven.

THE SALUTARAS DRUG & CHEMICAL Co., 1707 South Halsted St., Chicago, Ill., has been incorporated with a capital of \$5,000, to manufacture chemicals, drugs, etc. The incorporators are M. K. Wood, Stanley Darguzis and William Picktorman.

THE GARDNER-HART CHEMICAL CORP., Wilmington, Del., has been incorporated under state laws with capital of \$1,000,000, to manufacture chemicals and chemical by-products. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

THE GLO-RITE Co., Camden, N. J., has been incorporated with a capital of \$100,000, to manufacture polishes and kindred specialties. The incorporators are Edward S. Gille, James D. Eastnick and Harold W. Bennett, 45 North Third St., Camden.

THE SAGAMORE OIL CORP., Grandfield, Okla., has been incorporated with a capital of \$100,000, to manufacture petroleum products. The incorporators are Homer D. Cris, and W. S. Hamilton, both of Grandfield; and H. P. Downs, Tulsa, Okla.

THE SOUTHBRIDGE FOUNDRY Co., Southbridge, Mass., has been incorporated with a capital of \$30,000, to manufacture iron, steel and other metal castings. Frank S. Mills is president; and Arthur A. Allard, Southbridge, treasurer.

THE M-S POLAR-PROOF Co., Room 623, 53 West Jackson St., Chicago, Ill., has been incorporated with a capital of \$10,000, to manufacture varnishes, polishes, carbon removers, etc. The incorporators are John F. Ashworth, Judson G. Hancock and Robert M. Sherritt.

RESPRO, INC., Cranston, R. I., has been incorporated with a capital of \$100,000 to manufacture rubber products. The incorporators are Eugene A. Kingman, Walter A. Edwards and Kenneth J. Tanner, all of Providence, R. I.

H. MURDOCH & Co., Wilmington, Del., has been incorporated under state laws with a capital of \$100,000, to operate a metal smelting and refining plant; converting ores, etc. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE HEINEMANN & MOSCH GLASS & MIRROR Co., Newark, N. J., has been incorporated with a capital of \$50,000, to manufacture glass products, mirrors, etc. The incorporators are Otto Heinemann, Joseph Mosch and Frank Prasch. The company is represented by Howard Ishewood, 738 Broad St., Newark.

THE HERCULES CHEMICAL Co., Wilmington, Del., has been incorporated with a capital of \$100,000 under state laws, to manufacture chemicals and affiliated products. The company is represented by Franklin L. Mettler, 832 Market St., Wilmington.

THE FAIRMONT OIL Co., Woonsocket, R. I., has been incorporated with a capital of \$25,000, to manufacture oil products. The incorporators are A. E., R. A., and Lumina D. Bonin, all of Woonsocket.

THE ARTCHAFT PAPER BOX Co., 154 Whiting St., Chicago, Ill., has been incorporated with a capital of 250 shares of stock, no par value, to manufacture paper boxes and containers. The incorporators are James H. Cartwright, Jr.; Harold Beacon and R. S. Tuthill.

THE NEW JERSEY LEATHER GOODS Co., Jersey City, N. J., has been incorporated with a capital of \$100,000, to manufacture leather products. The incorporators are Herbert W. Royal, Edwin G. Adams and Herman B. Welch, 542 Palisade Ave., Jersey City.

THE RELIANCE OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000, to manufacture petroleum products. The incorporators are F. G.

Howland, L. Volk and G. J. Knight, all of Los Angeles. The company is represented by Carnahan & Clark, 756 South Broadway, Los Angeles.

THE RIO GRANDE PAINT Co., Laredo, Tex., has been incorporated with a capital of \$15,000, to manufacture paints, varnishes, etc. The incorporators are W. L. Guyler and E. H. Buenz, both of Laredo.

THE GREAT SOUTHERN STEEL Co., Chicago, Ill., has been incorporated under Delaware laws with capital of \$105,000,000, to manufacture steel products. The company is represented by Charles E. Pain, First National Bank Bldg., Chicago.

GEORGE J. YOUNG, INC., Brooklyn, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts, drugs, etc. The incorporators are George J. and R. Young. The company is represented by I. Cook, 189 Montague St., Brooklyn.

Capital Increases, Etc.

THE OCCIDENTAL OIL Co., Mexia, Tex., has been incorporated with a capital of \$500,000, to manufacture petroleum products. The incorporators are Frank Smith, S. E. Colgin and A. E. Wilder, all of Mexia.

THE POLO CHEMICAL Co., 2824 West Chicago Ave., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are Michael Schwetz and Leon Segel.

THE EASTERN ALUMINUM Co., Pittsburgh, Pa., has been incorporated with a capital of \$300,000, under Delaware laws, to manufacture aluminum and other metal products. The incorporators are George V. Brooke, Pittsburgh; John J. Hughes, New Florence, Pa.; and J. V. Hughes, Johnstown, Pa.

THE TRINITY OIL CORP., Dallas, Tex., has been incorporated with a capital of \$400,000, to manufacture petroleum products. The incorporators are Harry Pennington, Frank D. Halm and J. W. Ricker, all of Dallas.

THE COMMERCIAL CHEMICAL Co., 23-25 Light St. Baltimore, Md., has been incorporated with a capital of \$10,000, to manufacture chemicals and chemical byproducts. The incorporators are Edward S. Tyler, Charles E. Callis and William F. Hammond.

THE WEST BRANCH TANNING Co., Philadelphia, Pa., has been incorporated with a capital of \$5,000, to manufacture leather products. W. S. Anderson, 2241 North 53d Street, is treasurer.

THE CAFICO CHEMICAL Co., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of \$50,000, to manufacture chemicals and chemical byproducts. The company is represented by the Capital Trust Co., Dover, Del.

THE OIL DESULPHURIZING CORP., New York, N. Y., has been incorporated with a capital of \$1,500,000, under Delaware laws, to manufacture refined oil products. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE MUTUAL PETROLEUM CORP., Adrian, Mich., has filed notice of increase in capital from \$25,000 to \$100,000.

THE CLAY-GODSON CORP., 2413 Third Ave., New York, N. Y., has filed notice of dissolution under state laws.

THE PURE OIL Co., 74 Broadway, New York, N. Y., has arranged for a preferred stock issue to total \$4,300,000, for general operations, financing, etc.

THE WARNER SUGAR REFINING Co., 79 Wall St., New York, N. Y., has disposed of a bond issue of \$6,000,000, the proceeds to be used for general operations, financing, etc.

THE NATIONAL LEATHER Co., 161 South St., Boston, Mass., has been reorganized with a capital of \$7,500,000, a reduction of \$22,500,000 from the former capitalization. Stockholders have approved plans for a preferred stock issue to total \$15,000,000.

THE PIERCE OIL CORP., 25 Broad St., New York, N. Y., has arranged for a bond issue of \$2,000,000, the proceeds to be used for general operations, financing, etc.

THE ELECTRIC ALLOY STEEL Co., Charlevoix, Pa., has perfected arrangements for a preferred stock issue to total \$750,000, the proceeds to be used for additional working capital, plant extensions and improvements, etc.

Following the acquisition of the APSLEY RUBBER Co., Marlboro, Mass., by the Firestone Tire & Rubber Co., Akron, O., notice has been filed of change of name to the Firestone-Apsley Rubber Co.

Industrial Notes

W. F. LEGGET, former advertising manager of the Webster Manufacturing Co., Chicago, has become associated with the Chemical Catalog Co. as Western sales manager, with headquarters in Chicago.

THE UNION SULPHUR Co.'s New York office is now located in the Frasci Bldg., 32 Rector St., a new 15-story building named in honor of the founder of the Union Sulphur Co.

J. DOL & CIE., 30 Rue Pertinax, Nice, France, inform us that they hold options on large deposits of bauxite in southern France.

THE INSULATION & SPECIALTY CORP. OF AMERICA, du Pont Bldg., Wilmington, Del., has been incorporated for the manufacture of insulating material known as fiber granite. The material will be produced in sheets, tubes and rods.

THE W. A. JONES FOUNDRY & MACHINE Co., manufacturer of power transmitting machinery, announces the appointment of Fred E. Holtz as its Milwaukee district representative. He will assume his new duties immediately, making headquarters in the First National Bank Bldg.

THE COMBUSTION ENGINEERING CORP., New York, announces the recent opening of two branch offices: One at 216 Latta Arcade, Charlotte, N. C., in charge of T. E. Nott; the other at Seattle, Wash., where it is represented by the Fryer-Barker Co., 1133 Henry Bldg.

THE CHLORINE PRODUCTS Co., Chicago, Ill., announces that it is now ready to market its line of electrolytic cells, gas compressors, gas controllers, condensers, etc., for the production of chlorine gas, caustic alkalis, hydrogen gas and liquid chlorine. W. M. Jewell is secretary of the company.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its seventy-fourth meeting at Toronto, Canada, Dec. 26 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

PERKIN MEDAL will be presented to William M. Burton by the Society of Chemical Industry at its meeting Jan. 13 at the Chemists' Club, New York.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Unemployment and The Cost of Production

AN EXCEPTIONALLY prominent chemical manufacturer made a statement a few days ago that bears repeating, for it directs our thought along some of the less frequented byways of industry. The theme of the discussion was the inefficiency of present-day labor, and to carry his point this manufacturer related an incident that occurred a year ago in one of his chemical plants. During the month of December that plant produced a certain chemical at a cost of, say, \$10 per ton. In the following month, with the same workmen receiving the same wages and working the same number of hours, the plant had an increased output of this chemical and the cost of production had dropped to \$7.50 per ton. The only new factor entering into the situation was that all during the month of January there had been an ever-increasing crowd outside the factory gate, whereas in the preceding month the plant's employment bureau had been forced to take the initiative in obtaining even a few necessary replacements. In other words, the potential competition of those men outside the gate and the fear of being replaced by lower-priced men had the effect of stimulating the workers to increased production and greater efficiency.

But not long ago a famous British manufacturer, who is also a large employer, visited this country and, among other things, outlined a program of suggested reforms in relations between employer and employee. These he maintained were essential to material progress and represented the only real solution to the problem of industrial unrest. Prominent among his recommendations was the appeal to remove the menace of unemployment and the feeling of economic insecurity which is widely prevalent among the workers.

At first blush it would appear that the actual demonstration in the American factory disproved this part of the Englishman's theory. But is this the case after all? The possibility of unemployment served as a temporary stimulus to increased efficiency in this chemical plant, but are there not other more constructive ways by which this could have been accomplished? For instance, one of the outstanding features in the British manufacturer's program was the suggestion that the worker should have some tangible interest in the results of his labor and that where practicable he should share directly in the profits of the business. Another arrangement which has worked out satisfactorily in some plants is the periodical bonus based on production. In fact anything which tends to promote a closer understanding and a more intimate relation between the men inside the gate and their employer is in the interest of greater output and increased efficiency.

There will always be shirkers and inefficient workmen to retard progress and slow up production, but the

future holds much in store for the far-sighted manufacturer who succeeds in convincing the men inside the gate that all are working toward a common goal and that their mutual success or failure is entirely dependent on the combined efforts of the employer and the employed.

Are Colleges Over-Supplying Chemists?

OF ALL the laws of economics the dabbler in the subject usually unversed in business is most familiar with that governing the supply and demand of commodities. Having as a rule only a hazy idea of modern industry and no comprehension of how this law is dependent on many others, he proceeds glibly to generalize on "supply and demand" in relation to professional knowledge also. This forces him to consider the chemist or engineer as an inanimate thing without free choice, without "time-binding" or even "space-binding" characteristics, and immediately leads to a discussion of unionism, licensing or other methods of tampering with these laws.

The man of brains and technical training must in his very soul resent being classed as one of a number. If he's worth his salt he sincerely desires to be different and better, to remain the individual—not one of a class. He abhors the idea of unionizing and licensing.

Now, if we are to discuss an over-supply of chemists, thinking of the chemist purely as a laboratory worker, which unfortunately is the popular conception, such an over-supply does exist and always will exist. For the laboratory worker is merely on the first rung of the ladder. He parallels the draftsman in the engineering field and the test-shop man in the electrical field. Men are turned out of our technical courses and naturally are forced to crowd around the first step.

But industry needs these apprentices badly, and the chemical industry above all others requires more men with chemical training who can be absorbed in the many departments outside the laboratory. As these chemists become operating men, engineers, salesmen and executives, the industry is bettered and the economic return to the individual is, therefore, greatly increased.

Industry will accept them as theorists, but demands of them the ability to grasp the business side. There is no time in a four-year course to make business men of chemists, and it should therefore not be attempted. However, our teaching staffs may help the situation by putting the student in the proper frame of mind to see this aspect and talk less of fundamental research.

The electrical, mining and metallurgical industries have progressed rapidly because of their absorption of highly trained men in every branch of the work. Many hundreds of men are received from the colleges and turned to fit their places in these industries every year. Electrical teaching staffs do not prattle of research. No

more need the chemistry professors. The process industries are fearfully short of the type of technically trained man willing to seize opportunity in all branches.

Wouldn't it be better if our colleges held out a vision of science applied to industry, leaving research to the occasional brilliant mind that shows special adaptability? Industry can still absorb a large number of chemists of varied abilities.

Limiting the Activities Of Trade Associations

"**N**OW watch for the trade associations to fade away into nothing," was the comment offered by a close observer after the United States Supreme Court had rendered its decision on Dec. 19 in the case of the American Hardwood Manufacturers Association. In effect this association is told that the maintenance of open-price information is practically a restraint of trade and an effort to stifle competition and fix prices. On this ground the Supreme Court ruled that such practices must be discontinued.

For some time there has been little doubt in the minds of close students of association affairs that the open-price agreement would sooner or later be condemned; now the condemnation comes from the highest tribunal of the land and in no uncertain language. The decision will, of course, not at all affect scientific and technical societies that deal with matters of research and investigation or with matters of resource or manufacturing procedure. However, it will vitally affect those industrial groups that attempt to influence trade or commercial practices. In fact it should prove of considerable importance in guiding the activities of the newly organized Synthetic Organic Chemical Manufacturers Association.

Two association activities now distinctly in disrepute in Washington are "lobbying" and "open-price" agreements. There is much splendid work that can be done without dangerous intrusion upon these two fields of endeavor, and there is no doubt that the newly formed chemical organization can accomplish many helpful results. The chemical industry, because of its rapid growth and unnatural development, has failed to lay the proper stress on modern methods of cost finding, merchandising and other business problems on which a trade association might be expected to offer constructive criticism and advice. The study of foreign competition and of market possibilities at home and abroad is also a legitimate activity for co-operative work. Furthermore, there is a definite need for a unified organization to represent the chemical industry in its contact with the Department of Commerce, the Tariff Commission and other governmental agencies. The Bureau of Foreign and Domestic Commerce, under Mr. HOOVER'S guidance, is offering valuable assistance to industries that are willing to pledge whole-hearted co-operation. Can the chemical industry afford to stand aloof?

These are but a few of the many activities that are open to an association in the chemical industry. However, it is not unseemly, perhaps, to sound warning that the decision just rendered by the Supreme Court has placed one very definite limitation on the co-operative work which industry may legitimately undertake through the medium of the trade association. To ignore this decision will not only embarrass the association but will also damage any cause, however worthy it may be, which the industry hopes to serve.

Coke Byproduct Output Misinterpreted

THE GREAT decrease in output of coke during the past twelve months as compared with the large production of 1917, 1918 and 1920 has given rise to some confusion as to the effect upon production of byproducts. The cause for this confusion is easily understood; for those who have examined only totals of coke production have apparently forgotten that these totals do not indicate at all clearly the byproduct part of the business. In fact they are very misleading with respect to byproducts such as ammonia, tar and light oil, for the greater part of the fluctuation in coke totals is caused by the variation in beehive output, which, of course, does not at all affect the byproduct part of the business.

The peak of coke production was reached in 1918, when an average of slightly over 4,700,000 net tons of byproduct and beehive coke was made per month. Following the close of the war, there was a distinct falling off in the total, so that in 1919 the monthly average was over a million tons less than during the previous year, but most of this decrease was on beehive coke, the decrease on byproduct coke output being less than 4 per cent. The following year there was an increase in both beehive and byproduct output, but it was only slight for beehive and very marked in the case of byproduct. As a consequence of this, in 1920 the monthly average beehive coke production was less than two-thirds that of 1917, whereas the byproduct coke production for the same year was the greatest in the history of the industry.

During the present calendar year there have been, of course, large decreases of output of both kinds of coke, and only during the last few months has there been a tendency to increase again toward "normal." However, in no case has the byproduct coke output fallen below 50 per cent of the monthly average production for the previous year, which, as mentioned above, was the greatest ever recorded. The latest figures, those for November, 1921, show about 70 per cent of the monthly average production of 1920. During the same period, however, the output of beehive coke was less than 30 per cent of the 1920 monthly average and less than 20 per cent of the 1917 monthly average.

It is inconceivable that coke ovens should be operated without production of byproducts in more or less fixed ratio to the coke produced. In other words, for every million tons of coke made we can expect substantially uniform output of tar, ammonium sulphate and light oil. Whether this million tons of coke be made during a season of great activity or during a period of slack operation. The ratio, of course, is not exactly the same, for different coking periods affect the output of each of the byproducts somewhat; but the ratio for practical purposes is nearly enough uniform to permit us safely to draw conclusions as to these secondary products. It is clear, therefore, that no one is justified in assuming that the byproduct output—tar, light oil and ammonium sulphate—will fall in the neighborhood of 25 or 30 per cent of last year's production, as some seem to think would be the case. The output probably will be in the neighborhood of 65 or 70 per cent of the 1920 totals, for the byproduct coke output of the period will probably be of this order of magnitude. The proper interpretation of these facts is of great importance to the industries which depend upon the coke-oven operations of the country for their raw materials.

Work and

Employment in 1920

EXAMPLES of "how not to do it" are generally considered very useful. They are informing, while they do not circumscribe initiative as do examples of how to do it. We have already learned much from the year 1920 as to how not to do it, and now comes the preliminary report of the Bureau of the Census on gainful employment in 1920 to add to this knowledge.

We find from this report that we have some things to unlearn. A very popular idea has been that in 1920 a great many persons were receiving emoluments, including salaries and something called by the undignified and almost opprobrious title of wages, and that the chief thing wrong was that a great many were not working hard for the emolument received. Even that, however, was not the case, for the census report shows that a smaller percentage of the population was engaged in gainful occupation in 1920 than in 1910. There had been an increase in the proportion in each census up to and including that of 1910, but the 1920 proportion is almost precisely the same as that for 1900. The proportion is figured not against the total population but against the population ten years and more of age. The percentages have been: 1880, 47.3; 1890, 49.2; 1900, 50.2; 1910, 53.3; 1920, 50.3. So there is another good story gone wrong. Not as many were holding jobs, not to speak of working.

The Bureau of the Census in its preliminary report intimates that a considerable part of the apparent decrease in the proportion may arise from the 1910 census having been on April 15 while the 1920 census was of January 1, whereby the shown decrease in farm laborers might be accounted for. The common talk, however, was that men had gone away from the farm and got jobs in town, and furthermore it is to be noted that the larger decrease from 1910 to 1920 was in females.

The matter of females in employment is another thing suggesting we have something to unlearn. Most of us have heard so much about females replacing males in employment right along, and particularly on account of the war, that it has been difficult to avoid concluding that the contention must be correct. Not so, according to the census figures. Of the females ten years of age and over 23.4 per cent were gainfully employed in 1910 and 21.1 per cent in 1920, while of the males of the same age the proportions were 81.3 per cent in 1910 and 78.2 per cent in 1920. Thus the female proportion decreased 10 per cent and the male proportion only 4 per cent.

There was nothing particularly startling about industrial conditions on April 15, 1910, when the previous census was taken. We were going along and tending to business. We were not extremely or abnormally active, and 53.3 per cent of the male population ten years of age and over was gainfully employed. January 1, 1920, the proportion was only 50.3 per cent. In addition to a great many who were "gainfully employed" but were loafing more or less in this gainful employment (the census did not attempt to report how much real work they were doing), it now appears that there were a good many who ought to have been working and who did not even have jobs, presumably because they did not want to have jobs. The total number gainfully employed was 8,549,399 females and 33,059,793 males, or 41,609,192 altogether. Now and then there is a little talk—fortunately it shows a tendency to increase in

volume—about the "rights of the public" in labor disputes, the unions having a total membership of say 5,000,000 or less. When "the public" is mentioned in this connection it does not mean simply those who do not work, but includes the more than 35,000,000 persons who are gainfully employed but do not seek to get the gain by striking and threatening to strike.

Wildcats in

Western Texas

ONE of the outstanding national problems is the gradual impoverishment of the soil. Continuing our present agricultural practices will be to court serious economic difficulties; the problem of fertilization must be solved. Continued impoverishment of the soil will cause us to depend for our exports more and more upon the irreplaceable mineral resources available in limited quantities and less and less upon those food-stuffs which are annually renewed.

It is of more than passing interest, therefore, to study the possibilities of development in this country of natural potash supplies of all types. In every case where there appears reasonable ground for belief that potash deposits occur no time should be lost in exploration to determine their presence, their extent and their workability. Until some commanding percentage of our annual need can be supplied from domestic sources, we can never feel entirely safe against excessive charges by the producers who control the German and Alsatian supplies.

In this issue Professor UDDEN gives illuminating information regarding the possibilities of potash in Texas. He urges, and quite properly, exploration to determine the thickness and the extent of potash-bearing beds which are known to exist at least in small areas and in thin layers at widely separated regions in his state.

In Professor UDDEN's recommendation, the U. S. Geological Survey also heartily concurs. But the Survey also issues a warning that should be carefully heeded. In a recent announcement given wide circulation, it said:

To protect the public from misrepresentation and fraud by unscrupulous promoters and sellers of stocks based on potash deposits in western Texas the United States Geological Survey, Department of the Interior, states that the potash deposits there, instead of being 1,100 or even 300 ft. thick, as represented by the promoters, have not yet been proved to be of workable thickness or of commercial value. Rich potash salts, comprising the mineral polyhalite, which were deposited in association with great thicknesses of rock salt and gypsum in "red beds," as in Germany, and, in fact, at the same time as the German deposits, have been discovered by representatives of the United States Geological Survey and the Texas University Bureau of Geology and Technology in a co-operative search, but though this discovery, which was made public early in June, is encouraging and interesting, the practical question whether the deposits are thick enough to mine—that is, whether they are worth anything—is yet to be answered.

There is ample ground for optimism and certain need for exploration to give us exact information. But this is no time for the typical broadcast promotion of stock such as that which has been undertaken by certain persons obviously serving their own interest, not that of the general public. It should be the effort of technical men upon every appropriate occasion to encourage these scientific projects recommended by state and federal authorities; but they will also do a public service if they will repeat the warning which the Geological Survey has issued.

Hardness of High-Speed Steel

Hardness of High-Speed Tool Steel at Moderate Temperatures, Hardness in the Cold After Various Heat-Treatments, and Cutting Efficiency Determined in an Effort to Predetermine the Usefulness of a Modern Machine Tool

BY A. H. D'ARCAMBAL

Metallurgist, Pratt & Whitney Co., Hartford, Conn.

IT IS interesting to read the hardening recommendations for high-speed steel given in the different tool steel catalogs. Some manufacturers recommend an extremely high quenching temperature, with no subsequent tempering; others advocate a high quenching temperature with 400 to 600 deg. F. (204 to 316 deg. C.) drawing heat; a few recommend drawing to 1,050 to 1,100 deg. F. (566 to 593 deg. C.) after quenching from a high temperature; still others advise a lower quenching temperature; one or two recommend pack hardening or salt bath hardening; while one catalog states that drawing to 900 deg. F. (482 deg. C.) in an oil bath produces beneficial results.

In tests just completed by the writer on the best-known brands of high-speed steel made in this country and abroad, the analyses of which are shown in Table I, every brand of tungsten high-speed steel responded in the highest degree to a high quenching temperature followed by a draw at 1,100 deg. F. (593 deg. C.). The treatment recommended by Taylor and White in 1900 was to quench from a temperature close to the fusing point of the steel into a lead bath at 1,150 deg. F. (621 deg. C.), from there into oil or air quench, then drawing to 1,150 deg. F. (621 deg. C.). In the last 20 years the barium chloride process has been proposed, but is now little used, pack hardening was tried and still finds extensive use, especially abroad, and lead-bath hardening was tried and found wanting. Today, therefore, the majority of high-speed steel is being hardened in practically the same manner as recommended by Taylor and White in the beginning.

I have already stated briefly the advantages and disadvantages of the different hardening methods in an article entitled "Various Methods for Hardening High-Speed Steel". This contribution will attempt to show, by micrographs, hardness data, physical tests and cutting tests, the results produced by different hardening treatments on crucible and electric furnace high-speed steels of various compositions.

Fifteen bars (4½ in. rounds) listed in Table I were available. Steels numbered 1, 2, 5, 6, 7, 10, 12, 14 and 15 were selected for microscopic examinations, scleroscope tests, cutting tests, etc. As indicated in this table, some of these brands were the product of the crucible furnace, the remainder being electric furnace melted. Brinell hardness varied from 217 to 286; as a matter of fact, high-speed rounds of this size should be annealed to a Brinell hardness not greater than 240, but it seems to be the practice of some mills to conduct this final annealing operation in the shortest time possible, in consequence sending out a product not fully annealed. The majority of American tool steel mills rough turn their larger sized rounds, which is of considerable advantage to the consumer, since a smaller machining

tolerance may be used after the scale and decarburized surface have been removed. It also insures bars free from surface defects, for seams or laps are easily detected after turning. Not a bar of several received from abroad was rough turned.

Figs. 1 to 4 show the micrographs of this material as received in the annealed condition. Longitudinal sections were examined in order to reveal carbide segregations, envelope structure, etc. The only specimen showing complete freedom from these defects was No. 14, shown in Fig. 2. It was cut from a disk forged from No. 15 bar. The segregations and large carbide areas shown in Fig. 1 were completely broken up by this added working. Cutters made from hammered disks have greater cutting efficiency than cutters machined from the bar from which these disks were forged, as will be shown later. Bar 5 shows the worst segregation. Massive carbide areas and envelope structures cannot be broken up to any extent whatsoever by hardening; in fact, the only possible way to eliminate this undesirable structure is by further mechanical working.

Each of the bars of high-speed steel was machined into 4 x ½ x 1 in. hole, side-milling cutters. Blanks ½ in. thick were also cut from these bars; these blanks were then cut into disks, twelve of which were given the semi-muffle furnace treatment, twelve more the barium chloride treatment and the remaining twelve were hardened by the pack process.² These pieces were then drawn to different temperatures, carefully ground to remove

²For details of this treatment see "Various Methods for Hardening High-Speed Steel," by A. H. d'Arcambal, CHEM. & MET. ENG., vol. 25, No. 25, p. 1150, Dec. 21, 1921.

scale and decarburized material. A type "D" (dial reading) Shore scleroscope was used to determine the hardness of each sample, the scleroscope readings shown in Table II being the average of not less than ten readings. These results give the following information:

1. The three different methods of hardening all give about the same initial scleroscope hardness.

2. The majority of the samples quenched from the highest temperature (that is, Quenching A, the semi-muffle furnace treatment) showed a lower scleroscope reading after drawing to temperatures ranging from 600 to 1,000 deg. F. (316 to 538 deg. C.), but the samples drawn from 1,050 to 1,150 deg. F. (566 to 621 deg. C.) and in some cases as high as 1,200 deg. F. (649 deg. C.) showed the same or greater scleroscope hardness than in the undrawn condition.

3. Samples given the barium chloride and pack hardening treatments (B and C) also showed a lower scleroscope reading when drawn from 600 to 1,000 deg. F. (316 to 538 deg. C.) than in the undrawn condition. In a few cases the same scleroscope hardness as when quenched was obtained on samples drawn to 1,050 or 1,100 deg. F. (566 or 593 deg. C.). The falling off in scleroscope hardness after this temperature was passed was much greater in every case than found on samples treated in the semi-muffle furnace (Quenching A). The highest degree of secondary hardness was therefore obtained in test specimens quenched from the highest temperature.

NOTE.—Heat-treatment A: Heated to 2,300 deg. F. (1,260 deg. C.) in open fire and quenched in oil at 100 deg. F. (38 deg. C.).
Heat-Treatment B: Heated in barium chloride bath for twelve minutes at 2,100 deg. F. (1,150 deg. C.), and quenched in oil at 100 deg. F. (38 deg. C.).
Heat-Treatment C: Heated two hours in charcoal pack at 2,050 deg. F. (1,120 deg. C.)—requiring 3 hours to come to heat—and quenched in oil at 100 deg. F. (38 deg. C.).
Heat-Treatment D: Heated to 2,300 deg. F. (1,260 deg. C.) in open fire; quenched; drawn to 1,150 deg.; redrawn to various temperatures.

One of the samples that had been quenched from 2,300 deg. F. (1,260 deg. C.) and drawn to 1,150 deg. F. (621 deg. C.) was redrawn to temperatures up to 1,150 deg. F. (621 deg. C.), giving the results shown in Table II, Quenching 2-D. This shows that the scleroscope hardness obtained on redrawing a piece of hardened high-speed steel, which had been drawn to 1,150 deg. F. (621 deg. C.), would be a straight line, instead of showing a softened range from 600 deg. F. (316 deg. C.) to 1,000 deg. F. (538 deg. C.). Greater stability is thus produced by the high drawing treatment.

Microscopic sections were then cut from quenched specimens A, not drawn as well as after drawing to 1,100 deg. F. (593 deg. C.). These micrographs after etching for 2 minutes in a 5 per cent nital solution were then compared with micro-specimens of the corresponding pieces that had received the barium chloride treatment B. Fig. 4 shows these micrographs. A close study brings out the following points:

1. A high quenching temperature dissolves nearly all the carbides and tungstides³ which are not in massive or

³Honda and Murakami, "Notes on the Structural Constitution, Hardening and Tempering of High-Speed Steel Containing Chromium and Tungsten" (*Journal of Iron and Steel Institute*, No. 1, 1920), think that the fine white globules visible in high-speed steel under the microscope are a tungstide (Fe₂W) instead of a carbide for the following reasons: 1. The globules have the same behavior with chemical reagents as the tungstide found in carbonless iron-tungsten alloys. 2. Steels containing a definite quantity of carbon and chromium show an increase in these fine globules as the tungsten content is increased. 3. In steels containing a definite quantity of tungsten and chromium the globules do not increase with increasing carbon.

FIG. 3. KEY TO FIG. 4

envelope formation, producing a polyhedral structure; the resulting microconstituents are austenite, martensite and free carbides and tungstides.

2. Drawing to 1,100 deg. F. (593 deg. C.) produces a full martensitic structure and in general with suppression of the polyhedral crystals boundary markings.

3. High-speed steel quenched from 2,100 deg. F. (1,149 deg. C.) or lower does not possess the polyhedral structure of austenite (steel No. 5 being the exception), but reveals considerable quantity of free carbides and tungstides embedded in a martensitic matrix. Drawing

to 1,100 deg. F. (593 deg. C.) produces a slight amount of troostite.

4. Severe carbide segregations present in the annealed condition are not dissolved by the hardening treatment.

A comparison of the scleroscope data in Table II with these microstructures indicates that the greatest degree of secondary hardness is attained when the quenched material is partially austenitic. In other words, the higher the quenching temperature the greater the secondary hardening effect. The resistance to tempering is also dependent on the quantity of dissolved carbides.

Quenching high-speed steel from 2,300 deg. F. (1,260 deg. C.) apparently preserves austenite to only a slight degree, for the scleroscope hardness is about the same as for high-speed steel quenched from lower temperatures, which in turn produces a full martensitic structure. Hardened high-speed steel in the so-called "austenitic condition" is also quite strongly magnetic showing that the structure is by no means exclusively austenite. A sample of Mushet steel previously described,⁴ quenched from 2,200 deg. F. (1,204 deg. C.) was almost entirely austenitic, for the specimen was non-magnetic and possessed a scleroscope hardness of only 53.

HARDNESS AT HIGH TEMPERATURES

One often hears the question asked "How hard is high-speed steel at a dull red heat?"

In order to determine the hardness of hardened high-speed steels at temperatures from 400 to 1,200 deg. F. (204 to 649 deg. C.), tests were conducted as follows: Disks $\frac{5}{8}$ in. thick were cut from the 4 $\frac{1}{4}$ -in. round bars of high-speed steel as well as from a bar of carbon tool

⁴See CHEM. & MET. ENG., vol 25, No. 23, p. 1055, Dec. 7, 1921.

FIG. 4. MICROSTRUCTURE OF VARIOUS HIGH-SPEED STEELS AS RECEIVED AND AFTER VARIOUS HEAT-TREATMENTS. ETCHED 2 MIN. IN NITAL. $\times 350$.

steel, the disks then being halved. These disks were given the hardening treatments shown in Table III and tested for Brinell hardness at room temperature. They were then heated in a small electric muffle furnace, two at a time, with a pyrometer between the disks and touching them. The pieces were held at the desired temperature for a sufficient length of time to insure thorough soaking, removed from the furnace, placed at once on a steel block at the same temperature, and the Brinell hardness taken. The Brinell impressions were scaled immediately and the disk again placed in the furnace for the next higher temperature. After the test at 1,200 deg. F. (649 deg. C.) was taken, the pieces were cooled to room temperature and again tested.

It is necessary to use a ball after each test at 800 deg. F. (427 deg. C.) and higher as the ball was softened

the Brinell hardness of carbon tool steel at a dull red heat; see line 16-*I*.

6. High-speed steel disks given the high quench (treatment *E*), drawn to 1,200 deg. F. (649 deg. C.) and cooled gave the same Brinell readings as obtained before drawing. The disks given the pack treatment (*F*), and then drawn to 1,200 deg. F. (649 deg. C.), cooled and tested showed a softening of up to one hundred points. These results would be expected after studying the scleroscope data in Table II.

These Brinell tests at high temperature were a little disappointing in the results obtained, as the steel which showed the greatest cutting efficiency (No. 12) did not show a higher Brinell hardness at the different temperatures than some of the other brands. The steel which showed the poorest cutting qualities (No. 5), however, did show lower hardness at elevated temperatures.

CUTTER TESTS

It was decided to use heat-treated chromium-nickel steel, S.A.E. No. 3140, for testing these cutters. This alloy steel was given the same heat-treatment as this grade of material usually receives when used for airplane and automobile parts, and the resultant Brinell hardness varied from 262 to 277, the majority of the bars testing 269.

Chemical and physical properties follow:

Analysis	Per Cent	Physical Tests (Standard 0.505-In. Test-Piece)
Carbon.....	0.46	Elastic limit, 112,000 lb. per sq.in.
Manganese...	0.60	Tensile strength, 126,000 lb. per sq.in.
Chromium....	0.69	Elongation, 20 per cent.
Nickel.....	1.16	Reduction of area, 54 per cent.
		Brinell hardness, 269.

These 16 x 2½ x 1½-in slabs were ground on all sides after heat-treating to remove scale.

When milling material of this analysis and hardness, it was not necessary to run at such high speeds, feeds and depths of cut to break the tool down as when milling ordinary machinery steel or cast iron. Therefore the following was used: Speed, 130 ft. per minute; feed, 3½ in. per minute; cut, ½ in. deep; coolant, oil. An examination of each of these cutters showed that the cutting edges were worn, not burned down after being tested.

Referring to Table IV, it will be noted that all of these cutters were quenched from the semi-muffle furnace when they had attained a temperature of 2,300 deg. F. (1,260 deg. C.). They were carefully preheated at 1,600 deg. F. (871 deg. C.) before being placed in the high-speed furnace. The proper time to be given these cutters in the furnaces was obtained by independent experiments, then all the cutters were hardened in exactly the same manner.

Cutters tempered at 450 deg. F. (232 deg. C.) were drawn in an oil bath while cutters given the high drawing treatment (1,100 to 593 deg. C.) were first drawn in the oil bath to 600 deg. F. (316 deg. C.), then transferred to the niter bath at 650 deg. F. (343 deg. C.), and the temperature increased to 1,100 deg. F. (593 deg. C.). The cutters were permitted to remain for 10 minutes at this temperature, then were oil quenched. Cutters quenched from 2,300 deg. F. (1,260 deg. C.) into the niter bath at 1,100 deg. F. (593 deg. C.) were held in the bath for about 4 minutes, then oil quenched. As niter at this temperature attacks high-speed steel when quenched into the same and held for a considerable length of time, a lead bath is more suitable for the quenching medium.

Referring again to Table IV, it will be noted that

NOTE.—Heat-Treatment *E*: Heated to 2,350 deg. F. (1,290 deg. C.) in open fire; quenched in oil at 100 deg. F. (38 deg. C.).

Heat-Treatment *F*: Heated 1½ hours in charcoal pack at 2,050 deg. F. (1,120 deg. C.), (requiring 4 hours to come to heat), and quenched in oil at 100 deg. F. (38 deg. C.).

Heat-Treatment *G*: Same as *E*, except quenching followed by draw to 450 deg. F. (232 deg. C.).

Heat-Treatment *H*: Same as *E*, except quenching followed by draw to 1,100 deg. F. (593 deg. C.).

Heat-Treatment *I*: Heated to 1,480 deg. F. (805 deg. C.) for 10 minutes in lead bath and quenched into brine.

to a slight extent at the contact surface. In no case, however, did the balls flatten when in contact with the hot metal.

The following information is obtained from the data in Table III:

1. The higher the quenching temperature given the different brands of high-speed steel the greater the hardness at temperatures from 600 to 1,200 deg. F. (316 to 649 deg. C.).

2. The cobalt-molybdenum steel No. 5 shows considerably lower hardness at 600 to 900 deg. F. (316 to 482 deg. C.) than do the tungsten steels.

3. High-speed steel quenched and drawn to 1,100 deg. F. (593 deg. C.) (heat-treatment *H*) shows a greater Brinell hardness at temperatures from 600 to 900 deg. F. (316 to 482 deg. C.) than when quenched from the same temperature but only drawn to 450 deg. F. (232 deg. C.) (heat-treatment *G*).

4. All the high-speed steels given heat-treatment *E* (quenched from 2,300 deg. F.) have the same Brinell hardness, with one exception, at 1,100 deg. F. (593 deg. C.).

5. Hardened high-speed steel, while not as hard as hardened carbon tool steel, possesses almost three times

*Cutters made from forged blanks using No. 15 bar.

cutters containing somewhat higher vanadium (No. 12) showed the greatest cutting efficiency. The corners on these cutters were in good condition after the test, failure being due to the dullness. In passing it should be noted that each figure in the table represents the average length of cut made by two tools. In nearly all of the other cutters, the corners failed as well as the cutting edges. Steel No. 6, containing 3 per cent cobalt, ranked second, while the cobalt-molybdenum steel No. 5 showed the poorest cutting qualities. Cutters made from this brand of steel were given a higher quenching

temperature than recommended by the manufacturer, but it was decided to harden all of these cutters in exactly the same manner. Cutters No. 14, made from forged disks, showed about 25 per cent greater cutting efficiency than those machined from bar No. 15, from which the former were forged. Cutters No. 2, drawn to 800 deg. F. (427 deg. C.), which is in a soft range, as shown by Table II, showed less cutting ability than those made from the same bar, quenched from the same temperature but drawn only to 450 deg. F. (232 deg. C.). Other No. 2 cutters quenched into a niter bath at 1,100 deg. F. (593 deg. C.) performed about twice as well as those drawn to 450 deg. F. (232 deg. C.), but only a little more than half as well as when given the 1,100 deg. F. (593 deg. C.) draw.

One of the important points brought out by these cutter tests was the great increase in cutting properties produced by the high drawing temperature. The results obtained from cutters made of forged blanks, as compared with those machined from the hammered bar, verified the well-known fact that high-speed steel which has received sufficient working to break up carbide segregations and massive carbide areas will produce better tools than material containing them. As stated previously, these crystals will not go into solution on heating for hardening, and as the red-hardness and cutting efficiency are dependent on the dispersion of these carbides and tungstides, the greater cutting efficiency obtained from materials free from these segregations is accounted for.

Another interesting point brought out was the result obtained from cutters No. 2, quenched into a bath at 1,100 deg. F. (593 deg. C.) cooled from that temperature to room temperature and not drawn. The writer has been informed by two or three persons that quenching high-speed steel into a bath of 1,100 to 1,200 deg. F. (593 to 649 deg. C.) produces the same effect as oil quenching and drawing back to 1,100 to 1,200 deg. F. (593 to 649 deg. C.). As the results obtained in the cutter tests showed this was not true, we com-

FIGS. 5 TO 8. OIL VERSUS LEAD BATH QUENCHING. $\times 500$. ETCHED 3 MIN. IN 5 PER CENT NITAL SOLUTION
 Fig. 5—Oil quenched from 2,300 deg. F. Fig. 6—Fig. 5 after drawing to 1,100 deg. F.
 Fig. 7—Quenched from 2,300 deg. F. into lead at 1,100 deg. F.; held 30 min. and air cooled. Fig. 8—Fig. 7 after drawing to 1,100 deg. F.

pared the microstructure of $\frac{3}{4}$ -in. specimens of a high-speed steel⁵ after heat-treatments. The results obtained are shown in Figs. 5 to 8.

The specimen quenched into the lead bath at 1,100 deg. F. (593 deg. C.) and not drawn (Fig. 7) has exactly the same structure as the piece from the same bar quenched into oil and not drawn (Fig. 5). Drawing each of these pieces to 1,100 deg. F. (593 deg. C.) produced a full martensitic structure. It would seem that a temperature lower than 750 deg. F. (400 deg. C.), where a head evolution occurs on slow cooling curves of high-speed steel, must be attained before one can successfully obtain secondary hardening properties by reheating.

Hardness results were:

	Scleroscope Hardness	Brinell Hardness
Specimen oil quenched, but not drawn.....	93	652
Specimen oil quenched and drawn to 1,100 deg. F. (593 deg. C.).....	94	652
Specimen lead quenched and not drawn.....	93	652
Specimen lead quenched and drawn to 1,100 deg. F. (593 deg. C.).....	94	652

PHYSICAL TESTS

A $\frac{3}{4}$ -in. round bar of high-speed steel was cut into 7-in. lengths, the pieces centered and turned to $\frac{1}{2}$ in. round. These specimens were then quenched from 2,300 deg. F. (1,260 deg. C.) into an oil bath. Three of these test specimens were then drawn to 450 deg. F. (232 deg. C.) in oil, the remaining three pieces being drawn to 1,100 deg. F. (593 deg. C.). All of these bars were then ground to 0.656 in. and transverse tests⁶ conducted on the same, the results running as follows:

	Fiber Stress at Fracture, According to Formula, $p = \frac{eM}{I}$ Lb. per Sq. In.	Deflection, In.
Average of three specimens given the 450 deg. F. (232 deg. C.) draw.....	221,000	0.08
Average of three specimens, given the 1,100 deg. F. (593 deg. C.) draw.....	550,000	0.20

As can be seen from these results, the bars given the 1,100 deg. F. (593 deg. C.) drawing temperature required two and a half times the load to fracture them, although the hardness was identical (92). Under the microscope, the polyhedral structure was found to be still present in the material given the lower drawing temperature but the specimen drawn to 1,100 deg. F. (593 deg. C.) shows a martensitic ground mass with carbide globules. The results obtained from these transverse tests show that much greater toughness, with no sacrifice of hardness, is produced by the high draw. This greater toughness accounts to some extent for the increase in cutting efficiency obtained.

SUMMARY

A careful study of the data on hardness, micrographs, cutting tests and physical properties leads to the following conclusions:

1. The greatest degree of secondary hardness and the highest actual red-hardness is obtained in specimens given the highest quenching temperature (2,300 deg. F. or 1,260 deg. C.). The micrographs of the

quenched samples show that partial austenization has taken place in the steel given this high quenching temperature, with almost complete solution of the carbides and tungstides not in massive or envelope formation.

2. High-speed steel, quenched from a high temperature (2,300 deg. F. or 1,260 deg. C.) and drawn to 1,100 to 1,150 deg. F. (593 to 621 deg. C.), shows as great scleroscope hardness as in the undrawn condition, sometimes greater. Micrographs show that the small amount of austenite present in the undrawn material has changed to martensite.

Toughness and cutting efficiency have been increased from 100 to 200 per cent by the 1,100 deg. F. (593 deg. C.) draw. Cutters given a high quenching temperature, and drawn to 800 deg. F. (427 deg. C.) fail quicker than when given the 450 deg. F. (232 deg. C.) draw. One is led to expect that quenching from a temperature higher than 2,300 deg. F. (1,260 deg. C.) would give a lower initial hardness because of the formation of a larger amount of austenite. Drawing this material to 1,150 to 1,200 deg. F. (621 to 649 deg. C.) should develop the full martensitic structure with a considerable increase in hardness over that obtained in the undrawn condition. The drawing temperature at which this maximum hardness is reached would be higher than when quenched from the lower temperature, principally due to the greater resistance to tempering brought about by the larger amount of dissolved carbides.

3. High-speed steel quenched into a bath whose temperature is about 1,100 deg. F. (593 deg. C.), then cooled from that temperature to room temperature and not drawn, does not possess the same good properties as when drawn back to 1,100 deg. F. (593 deg. C.) after quenching. In other words, high-speed steel cannot be quenched and drawn in one operation. Taylor, in his experiments conducted 20 years ago at the Bethlehem Steel Co., found that it was necessary to draw his tools to 1,100 to 1,150 deg. F. (593 to 621 deg. C.) after they had been quenched in a bath at about the same temperature.

4. High-speed steel, in the larger size rounds, is very seldom free from segregations of massive carbide. As shown in a previous part of this article, these will not go into solution upon hardening. Tools made of material of this nature are of inferior quality, due to brittleness and deficient red-hardness caused by the large amount of undissolved carbides. Forged cutter blanks, which receive a large amount of working in all directions, are free from these segregations and thus produce better tools.

5. The scleroscope or Brinell hardness of a high-speed steel tool is no indication of its cutting qualities. Some of the cutters which showed the greatest cutting efficiency and some of the cutters which produced very little work showed exactly the same hardness readings. The file test is also a misleading one. A high-speed steel tool may be quite easily filed with a good file, but still do just as good work as a similar tool which is file hard.

In closing, the writer wishes to emphasize the fact that using material of the proper chemical analysis does not insure a good tool. If the steel is not fabricated correctly or if the tools are improperly hardened or ground, a poor product will result. However, a close control of all of these factors does insure a uniformly good product.

Vapor Pressure of the System Calcium Chloride-Water*

The Application of Dühring's General Law in an Investigation of the Boiling Points of Aqueous Calcium Chloride Solutions of Various Concentrations and Under Reduced Pressures Affords a Graphic Solution of Some Practical Problems in Vacuum Evaporation

BY E. M. BAKER AND V. H. WAITE

THIS paper is a report of an investigation of the boiling points of calcium chloride solutions at atmospheric and reduced pressures. The apparatus used for the determinations and the method of making the critical study are those described in a previous paper by the same authors.¹

Five solutions of the following concentrations were investigated:

- (1) 141.3 g. CaCl_2 per 100 g. H_2O .
- (2) 101.0 g. CaCl_2 per 100 g. H_2O .
- (3) 68.86 g. CaCl_2 per 100 g. H_2O .
- (4) 25.91 g. CaCl_2 per 100 g. H_2O .
- (5) Saturated solution.

The range of pressures over which the boiling points of the system were studied was from 100 mm. to 760 mm. absolute pressure.

Chemically pure calcium chloride was used for these determinations. Solutions were made up of about the concentrations desired, and the boiling-point curves were determined by the method described. In the case of the more dilute solution a sample of this liquor was then poured into a glass-stoppered sample bottle, which was then sealed with paraffin and held for analysis. In the case of the more concentrated solutions this method could not be used, since on cooling the CaCl_2 would partly or completely crystallize, often breaking the containing bottle. For these solutions the sample was taken by pouring a portion of the solution, while still hot, into a tared weighing bottle containing a weighed amount of water. The bottle was then weighed, sealed and saved for analysis. The results of the analysis were calculated back to the original concentration of solution. The standard gravimetric method for chlorine, using AgNO_3 , was used for determining the concentration of the various solutions. The solutions were tested to determine if any HCl had resulted from hydrolysis and had been given off with the vapor. Hydrolysis was found to be negligible. To make an error of 0.1 deg. in the boiling point the concentration as determined would have to be in error by 0.25 g. of calcium chloride per 100 g. of water, at the range where the boiling point changes most rapidly with a given change of concentration.

PROCEDURE FOR CONCENTRATED SOLUTIONS

Work on unsaturated solutions would have been carried to even higher concentrations than was done, if these solutions were not so viscous that there could be no assurance that at higher concentrations they would be of uniform concentration throughout.

In determining the boiling-point curve for the

saturated solution it was necessary to immerse the platinum resistance thermometer directly into the solution, as the solution was so extremely viscous that the pumping tube could not be made to work. Except for immersing the bulb of the thermometer in the solution, the method used was the same as for the unsaturated solution. Temperatures were taken both for ascending and descending pressures with an excess of solid CaCl_2 in the boiling-point tube in order to eliminate the possibility of supersaturation or undersaturation. The experimental values thus obtained for both the saturated and unsaturated solutions are shown in Table I.

EXPERIMENTAL VALUES AND THOSE IN LITERATURE

Most of the data given in the literature on the boiling points of CaCl_2 solutions can be classified into two groups:

- (a) The boiling temperature of solutions of a given strength at various pressures.
- (b) The boiling temperature at atmospheric pressure of solutions of different concentrations.

Fig. 1 shows the data of group *a* plotted by the method referred to in the previous article—i.e., for each solution of a given concentration, the temperatures at which the solution has certain vapor pressures are plotted as ordinates, against the corresponding temperatures at which water has the same vapor pressures, as abscissas. It is noticeable that the data given in the literature for boiling points of calcium chloride solutions at reduced pressures do not include solutions more strongly concentrated than 43 g. of CaCl_2 per 100 g. of H_2O .

Data taken from the literature are indicated by separate symbols for each worker. It will be noted that many of these values as plotted are erratic and do not fall on the curve. However, this is presumably due to experimental errors, as they do fall more nearly on the straight line curves than on any other smooth curve that could be drawn.

In Fig. 1 are also shown experimental data for the solutions investigated by the authors. The curves are lettered to indicate the concentration of each solution. The values for individual determinations are given in Table I and are shown in the graph by the large open circles. In the discussion of the apparatus in the previous paper it was stated that an absolute accuracy of 0.1 deg. C. could be expected in these determinations. The maximum variation of any of the above points from the straight lines as drawn is 0.1 deg. C., while most of the points do not lie more than 0.02 or 0.03 deg. C. from the respective straight lines.

For each concentration of solution represented in Fig. 1 the boiling temperatures of the solutions corresponding to the pressures at which water would boil at 100 deg. C. and 50 deg. C., were read off—i.e., at

the latter data being tabulated in Table III. The ordinates of Fig. 3 show the temperature at which the solutions would boil under some given pressure, plotted against the temperature at which water would boil under the corresponding pressure, as abscissas. For each of the solutions shown, the boiling points at 760 mm. and 92.3 mm. (boiling points of water 100 deg. C. and 50 deg. C.) were plotted, and straight lines were drawn between the two intermediate points. The corresponding curve for the saturated calcium chloride solution was also plotted directly from the experimental data. As here reproduced the scale is too small to permit Fig. 3 being directly used as a source of data, but it may be easily reconstructed on a large scale from the data of Table III. However, numerous values were read from this figure, and these are reproduced in Table IV, which shows the temperature at which calcium chloride solutions of various concentrations would have certain vapor pressures, between the limits of 100 mm. and 760 mm. pressure.

Since the curves A and B of Fig. 2 are based on comparatively few values determined by us, the same

140	1.0905	141.65	87.12
150	1.101	144.20	89.15

accuracy is not claimed for the data on the system as a whole, as tabulated in Table IV, as for an individual determination. The probable maximum error of the latter is 0.1 deg. C., while the corresponding error of values in Table IV may reach 0.2 or 0.3 deg. in extreme cases. An absolute accuracy of this order is quite sufficient for practically all technical purposes.

It will be noticed that the vapor pressure curve of water (data from Peabody's Steam Tables, 1910) is also plotted in Fig. 3. This curve may be used to give directly the vapor pressure under which a given solution will boil at a given temperature and *vice versa*. For instance, to find the vapor pressure corresponding to the boiling point at 90 deg. C. of solution of 100 g. CaCl_2 per 100 g. of water, extend across horizontally from 90 deg. on the temperature ordinate to the curve for the given concentration. Then, extending down vertically from this intersection, the temperature at which water would boil at the same pressure is found to be 61.85 deg. C. Or, if the pressure is read corresponding to the intersection of this abscissa with the curve for the vapor pressure of water, this pressure is found to be 162.3 mm. and is the pressure sought.

SOLVING SOME EVAPORATOR PROBLEMS

As a second simple illustration of the use of Fig. 3, assume that a calcium chloride solution is being concentrated in a single effect evaporator. Exhaust steam is available at a pressure corresponding to 105 deg. C. The minimum permissible temperature drop across the

heating surface to give the desired evaporator capacity is 20 deg. C. The evaporator is operated at an absolute pressure of 160 mm. What is the maximum degree to which the concentration of the CaCl_2 solution can be carried, and satisfy the above conditions?

From the ordinate of 160 mm. pressure, extend across horizontally to the vapor pressure curve for water, finding that water would boil under this pressure at 61.6 deg. C. Then extending up vertically on this abscissa (61.6 deg. C.) to the ordinate 85 deg. C., the concentration of the solution that would boil at 85 deg. C. under 160 mm. pressure is found by interpolation to be 85.2 g. CaCl_2 per 100 g. of H_2O . This is the concentration sought. The actual temperature drop is 105 deg. — 85 deg. = 20 deg. C., while the temperature drop for evaporating water under the given pressures would be 105 deg. — 61.6 deg. = 43.4 deg. C.

Or again, suppose it were desired to carry the concentration to 150 g. of CaCl_2 per 100 g. of water, in the above case, what would be the necessary temperature of the steam to have a minimum effective temperature drop of 20 deg. C. across the heating surface when the solution reached this concentration? The absolute pressure in the evaporator is 160 mm. Extending across horizontally from this pressure ordinate to the vapor pressure curve for water, it is found that water will boil at 61.6 deg. C. under this pressure. Extending up vertically from this abscissa of 61.6 deg. C. to the curve for a solution of 150 g. of CaCl_2 per 100 g. of water, it is found that this solution would boil under this pressure at 101.9 deg. C. Then to give an effective temperature drop of 20 deg. C., the temperature of the steam would have to be 101.9 deg. + 20 deg. = 121.9 deg. C., or 1580.8 mm. absolute pressure; whereas for evaporating water under like conditions, the steam would have to be under an absolute pressure of only 378.8 mm.

A bibliography of references on the vapor pressure of calcium chloride solutions is appended.

Acknowledgment is made of the financial assistance received from the National Research Council, which made possible this investigation.

Favorable African Market for American Products

Vice-Consul John R. Minter of Johannesburg reports in the Nov. 21, 1921, issue of *Commerce Reports* that not more than 3 to 5 per cent of the paints and varnishes consumed in South Africa are manufactured locally. Americans have been holding their own in the South African markets. Imports from the United States in 1914 constituted 28 per cent of the total imports of paints and varnishes, 40 per cent in 1919, and 40 per cent in 1920.

Copper-Cadmium Wire for Electrical Transmission

BY W. C. SMITH

Metallurgist, U. S. Metals Refining Co.

COPPER is the metal generally employed for electrical conductors. It combines several very desirable properties—for example, high electrical conductivity (second only to silver), fairly high tensile strength, resistance to corrosion and reasonable cost. It can readily be cast, rolled and drawn.

Copper wire of good quality should have a resistivity of less than 0.15535 ohm per meter gram at 20 deg. C. or a conductivity greater than 98.5 per cent, Matthiessen standard, annealed. The tensile strength of hard-drawn copper wire should be greater than 49,000 lb. per sq.in. for a wire 0.46 in. in diameter, and 67,000 lb. per sq.in. for a wire 0.040 in. in diameter. Wrought copper is completely softened (annealed) by being heated to a temperature of 175 deg. C. (350 deg. F.) for 72 hours, or in a few seconds when heated to a temperature of 310 deg. C. (600 deg. F.).

PROBLEMS FOR THE ELECTRICAL ENGINEER

Electrical engineers are constantly being confronted with problems, the solution of which requires the use of metallic conductors possessing properties not inherent to hard-drawn copper wire.

As examples, the tensile strength of copper wire limits the distance between supports; the low annealing temperature of hard-drawn copper wire limits the temperature to which the wire may be heated either by intention or by accident, and in many places where abrasion of wear is particularly heavy, copper is too soft to give satisfactory service. A large number of brasses and bronzes are on the market and are used more or less as electrical conductors because of some special property each one possesses. All of the special alloys have one great disadvantage—they are all of very much lower electrical conductivity than hard-drawn copper.

An alloy of rather unusual properties, and one unknown to the average engineer, is copper-cadmium. Wire drawn from copper containing a small amount of cadmium has a much greater tensile strength, is considerably harder, has a higher annealing temperature than a pure copper wire of the same size, and its electrical conductivity has been reduced to a lesser degree than for any other known alloy of equivalent tensile strength.

RESULTS OF LABORATORY TESTS

The results of some laboratory experiments made by the writer during 1918 and 1919 are shown in the accompanying curves of Fig. 1. In every case the wire tested was a No. 12 B. & S. gage (approximately 0.081 in. in diameter). The tensile strength tests were made on hard-drawn wire, and the conductivity tests were made on annealed samples.

Annealing was done by passing 150 amp. through each sample for 65 seconds. Preliminary experiments indicated that a complete anneal could be made under these conditions. A series of laboratory experiments on the annealing temperatures of copper-cadmium wire as compared with pure copper wire indicated that the annealing temperature of the copper-cadmium increased as the cadmium content was increased, and that a wire containing 1.10 per cent cadmium withstood a temperature

of 260 deg. C. (500 deg. F.) for $\frac{1}{2}$ hour, with only slight evidence of softening, while the pure copper wire was *dead soft* after the same treatment.

A hardness test made on a cast alloy containing 1.10 per cent cadmium indicated that the alloy was about 20 to 22 Brinell numbers harder than cast copper. No Brinell tests were made on wire, but it was observed that the alloy wires were somewhat stiffer and harder to file than wires of pure copper.

Mill tests indicated that wirebars containing up to 1.20 per cent cadmium could be hot-rolled, but when the cadmium content of the alloy was further increased the bars cracked in passing through the breaking down rolls.

The melting point of copper is approximately 1,083 deg. C. (1,980 deg. F.), of cadmium 321 deg. C. (609 deg. F.) and the boiling point of cadmium is approximately 778 deg. C. (1,332 deg. F.) This explains the

FIG. 1. STRENGTH AND ELECTRICAL CONDUCTIVITY OF COPPER-CADMIUM WIRE

failure of our first attempts to produce an alloy of uniform composition by the direct addition of cadmium to molten copper. Experimental work developed the fact that a uniform alloy could be produced by introducing the cadmium into the molten copper in the form of an alloy of copper and cadmium rich in cadmium. For this work alloys containing from 30 to 75 per cent cadmium have been used. The base alloy generally employed contains about 50 per cent cadmium. It was found that the base alloy could be produced from molten copper and solid cadmium with the loss of very small amounts of cadmium if the temperature were accurately controlled.¹

A number of lots of copper-cadmium wirebar were made by adding calculated amounts of copper-cadmium base alloy to known quantities of molten refined copper in a large ladle, and then casting the metal into wirebar molds. The wires drawn from the several wirebars of each cast were tested for tensile strength and conductivity. These tests indicated that uniform results could be expected.

Copper-cadmium wire has been successfully used for wireless aërials, long-span transmission wire and trolley wire.

Chrome, N. J.

¹The method of production of the base alloy and its use to produce copper-cadmium alloy of the desired composition is covered by U. S. Pat. 1,307,642 (June 24, 1919).

On the Discovery of Potash in West Texas

BY J. A. UDDEN

Director of Bureau of Economic Geology, University of Texas,
Austin, Texas

FOR some time it has been regarded as quite likely that potash may exist in association with the extensive salt beds underlying the west part of the state of Texas. In 1912 S. M. Swenson & Co. were drilling a deep well at Spur, in Dickens County, and this work seemed to offer an opportunity for making observations bearing on this question. Accordingly it was arranged that the Bureau of Economic Geology and Technology of the University of Texas should be permitted to collect and to make analyses of several samples of brines from this boring. These samples carried evidence of a more than normal amount of potash in the brine only from 2,100 to 2,200 ft. below the surface. An account of this was published on pages 82 to 90 in Bulletin 363 of the University of Texas.

In 1914 an opportunity was likewise presented to secure samples of salt from two borings in Potter County. These showed the presence of a potash-bearing red mineral at several depths. A report on these results was prepared and published in 1915. This was our Bulletin 17, entitled "Potash in the Texas Permian." Largely on the strength of the evidence in these observations, the U. S. Geological Survey undertook to drill a hole at Cliffside in Potter County, to obtain more definite information on the occurrence of potash in the salt beds in that vicinity. Very slight evidence of potash was found also in this exploration, the results of which were published in the potash report of the Survey for 1917. Later co-operation was arranged between our bureau and the U. S. Geological Survey and a man was engaged to get all information possible in the field on the occurrence of potash in association with salt in such wells as were being drilled for oil in the western part of the state. We have now had a co-operative man in the field for 3 years. Lately D. D. Christner, the joint representative of the two Surveys, has found potash in five new places in the Llano Estacado about 200 miles south of the first occurrences noted.

EXTENT OF THE POTASH-BEARING STRATA

The potash-bearing mineral is, in almost every case noted, a red salt, which is now believed to be polyhalite, at least in part. This mineral contains about 18 or 19 per cent of potash. The occurrence of this mineral in sufficient quantity in the drillings taken at considerable depths makes it appear desirable to investigate the size of the deposits. This can be done only by coring the salt beds. As the salt and potash are both soluble in water, the taking of cores through such beds requires special and expensive processes, and to obtain the results desired it should be done under competent scientific and technical direction. The latest five places where potash has been found are about 60 miles apart. It seems possible that the potash-bearing strata may extend the entire distance between these places and possibly up to the Panhandle. From a recent study by N. H. Darton, of the United States Geological Survey, it appears that conditions that may be considered favorable for the natural concentration of salt and also potash in the formations of the Permian, in which these salt beds occur may have been widespread, reaching possibly from western Oklahoma southwestward to the

Pecos River. The largest part of this area lies in our own state.

To summarize the evidence obtained showing the existence of potash in this state the following brief statements can be made:

In 1912 S. M. Swenson's boring at Spur, in Dickens County, gave a brine at 2,200 ft. below the surface, which contained 5.4 per cent of potassium, calculated as chloride.

In 1915 a boring at Boden, in Potter County, furnished some red salt, probably polyhalite, occurring somewhere between 875 and 925 ft. below the surface, and this red salt contained 9.2 per cent of potash, calculated as oxide.

In the same year the Miller boring in Potter County furnished at somewhere between 1,500 and 1,700 ft. below the surface some red salt that contained 6.1 per cent of potash calculated as oxide, and at some level below 1,700 ft. it had some colorless salt associated with anhydrite. This salt contained 10.5 per cent of potash, calculated as oxide.

Within the last 12 months, we have found in the Bryant boring in Midland County, in cuttings accumulated while boring from 2,405 to 2,425 ft. below the surface, a mixture of colorless and red salt, shale and anhydrite yielding 6.9 per cent of potash, calculated as oxide.

We have found in the early part of last spring in the La Mesa Oil & Gas Co.'s Burns No. 1 boring in Dawson County, at a depth of from 1,864 to 1,865 ft. below the surface a red salt which yields 10.8 per cent of potassium oxide.

In the Means well, in Loving County, about 40 miles north of Pecos, samples show 15.5 per cent of potassium oxide, coming from a depth of 1,000 ft., and there is 8 per cent of potassium oxide in samples from between 1,855 and 1,860 ft.

In the River well of the A. Pitts Oil Co., about 8 miles east of Barstow, in Ward County near the Pecos River, showings of 14.4 per cent of potassium oxide were obtained from samples taken at 1,600 ft. In a sample taken at a depth of 1,875 ft. in the same boring there was found 10.5 per cent of potassium oxide.

In the G. A. Jones et al. Long well, in the southeast part of Borden County, an analysis shows the presence of 22.9 per cent of potassium oxide in a picked sample from between 1,070 and 1,075 ft., and a picked sample from cutting between 1,075 and 1,083 ft. showed 17.68 per cent of potassium oxide. The sample from 1,115 ft., similarly picked, shows 6.59 per cent.

NEED OF SYSTEMATIC EXPLORATION

It is generally known that the salt beds of our Permian on the High Plains have resulted from concentration of water in the arms of the sea during a long period of time in the Permian age. The desiccation of these waters caused the potash salts of the brines to be precipitated last, whenever the points of saturation for these salts was reached. Evidently desiccation did not go far enough in many cases to precipitate the potash. We can scarcely expect that evaporation of such arms of the sea should continue through a long period of time, resulting in the laying down of a considerable number of salt beds and that desiccation should in every case have stopped short of precipitating the potash. In the many cases of partial or total desiccation indicated by the number of salt beds found in the Permian, it is more likely that the waters were in some

cases completely evaporated. Reasoning in this way, there is good ground for the belief that potash should exist in separate beds in that part of our Permian basin where most salt was precipitated. Our finding of potash salts in no less than seven wells, two of which are located in the Panhandle and five in the Llano Estacado, strongly tends to prove the correctness of the conclusion that widespread beds of potash exist in this region; but the observations that have so far been made give absolutely no information on the thickness of the potash-bearing beds. All we know is that there are such beds. To determine the thickness of the beds in order to find whether these deposits will prove of commercial importance, it will, as already stated, be necessary to drill special holes for that purpose and to take out cores of the beds, to be carefully examined. As I look at it, the time is now at hand when our information justifies such explorations. It is scarcely conceivable that potash-bearing beds should occur for 300 miles and that they should not at some place be of sufficient thickness to be profitably mined. Such explorations will require large capital, so that a number of holes, a half hundred if necessary, can be made in different parts of the area indicated by the observations now made, before the location for operations and the method of mining are to be determined.

Austin, Tex.

Strengthening of Zinc and Zinc Alloys by Compression

The dearth of copper during the war forced the Continental Powers to try to discover total or partial substitutes for this metal, and several papers on these attempts and researches have recently been brought before the Deutsche Gesellschaft für Metallkunde. In one of these communications Dr. Ing. Hanszel, of Berlin, deals with the improvement of brass and of zinc by compression. Various brasses containing from 57 to 61 per cent of copper, about 1 per cent of lead and about 3.5 per cent of total impurities were improved by compression after reheating; but they were not sufficiently uniform to be quite reliable. Zinc containing about 1 per cent of lead, with traces of iron and cadmium, was so much strengthened by high compression that it appeared almost a different metal with its grainy, partly fibrous structure. Compression of zinc had been in use in the Hohenlohenhütte, Silesia, before the war. The ingots should be perfect, the tops and pipe must be discarded, and the ingot remelted before compression; cracks in the ingot are not really welded up by compression. When objects like stoppers with threaded bolts are pressed in the molds, sharp corners should be avoided, and the profile rounded off first and finished on the lathe; the zinc flows, and the lines of flow are diverted at sharp corners. The superior qualities of this compressed zinc are, moreover, confined to the temperature range 0 deg. to 50 deg. C., but the metal seems to bear the winter cold well. Storage for several years did not deteriorate several of the alloys of zinc with copper and aluminum, which also passed the repeated gage tests. Among these the alloy of zinc with 6 per cent of copper and 5 per cent of aluminum found favor in Austria and was, later, with only 2.5 per cent of aluminum, manufactured also at Spandau. Zinc alloys with up to 30 per cent of Al were also tried, and the alloys were tested in large quantities, both mechanically and metallographically. These metals and alloys were mainly utilized in ammunition works.

The Electrolytically Produced Calcium-Barium-Lead Alloys Comprising Frary Metal*

Equilibrium Diagram and Microstructure of Barium-Lead and Calcium-Lead Alloys—Ternary Alloy Hardens and Strengthens on Aging; Is Hard at Moderate Temperature; Can Be Melted Without Change in Analysis, and Is a Very Fine Bearing Metal

By WILLIAM A. COWAN, L. D. SIMPKINS AND G. O. HIERS
National Lead Co. Research Laboratories

DURING the early part of the World War when, on account of the large amount of shrapnel bullets being made from antimonial lead, there was a shortage of this material and of antimony, a substitute was eagerly sought. It was following this that Drs. F. C. Frary and S. N. Temple procured patents¹ covering alloys of lead with barium, calcium and other elements. The calcium-barium-lead alloy was found to have remarkable qualities as a bearing metal, showing the characteristic structure and necessary properties required for such service. The Bureau of Standards² made a report of physical and service tests on a submitted sample of the alloy showing better results than with genuine babbitt and stating that it possessed all the requisites of a good bearing metal. The alloy has been manufactured on an extensive scale for this and other uses by the United Lead Co.

METHOD OF PRODUCTION

The method of production can be classified as electrodeposition from fused salts, since the process consists in electrolyzing the fused chlorides of barium and calcium over a bath of molten lead as cathode. In the preparation of alloys of barium and calcium by this method the electrodeposited metals are taken up by the lead, and the resulting alloy is obtained as the desired product.

There has been previous mention made in the literature³ of similar methods of preparing either pure metals or alloys by electrolysis of fused salts. Such elements as sodium, calcium, magnesium, zinc and aluminum have been prepared as pure metals in this way, the principle involved being essentially the same in all cases, but differing in difficulties encountered. These are owing to differences in melting points and dissociation phenomena of the salts, as well as to differences in the properties of the pure metals produced.

Preparation of metallic calcium from fused calcium chloride has been accomplished only after overcoming numerous difficulties. It was prepared on a fairly large scale during the war, and has also been made experimentally both by the Westinghouse Manufacturing & Electric Co.⁴ and by the General Electric Co. However,

owing to the difficulties in producing pure metallic calcium free from chlorides, carbides and other impurities, it is not economical to produce an alloy by first preparing the calcium separately and adding it to molten lead. There would also be trouble in commercial manufacture of an alloy by mixing the pure metals in this way owing to the difficulty of obtaining complete solution of the calcium in the lead without loss by oxidation of the calcium. In attempting to produce metallic barium electrolytically it has been found that the resulting barium gathers around the cathode in droplets which fail to coalesce, and therefore it is not economical to attempt to obtain the barium in a pure metallic state. However, with the use of a bath of molten lead as a cathode, this difficulty is not encountered, since the barium alloys readily with the lead as it is produced.

MANUFACTURE

Calcium-barium-lead alloys suitable for bearing metals and other purposes, together with the process of manufacture, are described in United States patents.⁵

FIG. 1. BATTERY OF ELECTROLYTIC POTS FOR MANUFACTURING FRARY METAL; UNITED LEAD CO., KEOKUK, IOWA

The process of manufacture, as carried out by the United Lead Co. operating under these patents, consists in the use of a series of iron pots of about 2 tons capacity each. These are partly filled with pig lead of high quality. As shown in Fig. 1, each pot of the series is set in brickwork containing a hearth which is fired with coal. After the pots have been filled with pig lead all the hearths are fired until the lead is melted. On top

FIG. 2. INTERIOR VIEW, UNITED LEAD CO.'S PLANT FOR FRARY METAL

of the molten lead is placed a layer of the mixed salts of calcium and barium chlorides of high purity, in such proportions as to give a low melting point. This layer of chlorides is usually about 3 or 4 in. thick. Each pot is equipped with a graphite anode at the center which can be raised or lowered by a chainblock.

In starting, the anodes are inserted in the chlorides and a direct current thrown in. There is sufficient resistance in the salts to produce enough heat to fuse the mixed chlorides. The temperatures in the pots are controlled by raising or lowering the anodes. Under the influence of the electrolytic action, the fused salts are decomposed and the resulting calcium and barium are absorbed by the molten lead. There is a tendency toward fogging and arcing, and considerable amounts of the calcium and barium form carbides which reduce the efficiency of the process, therefore requiring approximately 3 days of electrolysis to produce a lead alloy containing 2 per cent of the alkaline earth metals. The fused chlorides and carbides tend to freeze at the surface, forming a hard crust, particularly around the periphery of the interior of the pots. If this forms too near the anode, it may need to be broken down in order to give proper conditions; otherwise it is advantageous, acting as an insulator and thus preventing loss of current which might pass through the fused electrolyte from the anode directly to the iron pot instead of to the molten lead. Absorption of the calcium and barium by the lead appears to follow a logarithmic curve—that is, it requires much longer than 3 days to produce an equal increment of absorption of the alkaline earth metals. This is probably due to an equilibrium set up between the lead and the alkaline earth metal on the one hand, and in the decomposition of and reactions in the fused electrolyte on the other hand.

After the electrodeposition has been under way for some time, samples of the molten metal are removed, and the barium and calcium contents determined, additional samples being taken from time to time until the desired composition is obtained. When the proper amounts of calcium and barium have been absorbed by the lead, the current is shut off and the molten alloy is run out from the bottom of each pot into a carrying ladle of equal capacity, which is conveyed by an overhead crane. By this means the metal from the whole series of pots is emptied into a large mixing kettle shown in Fig. 2, where it is thoroughly agitated and

further alloying ingredients are added. The resulting alloy is then sampled and cast in water-cooled ingot molds.

FRARY METAL

The alloy thus produced by the United Lead Co. has been termed "Frary metal." As disclosed by the patents, it is essentially a ternary alloy of lead, barium and calcium, with the addition of small amounts of other elements. It contains up to 2 per cent barium and up to 1 per cent calcium, the remainder consisting almost entirely of lead. As much as 0.25 per cent mercury and smaller amounts of other elements may be added.

METALLOGRAPHY

In studying the metallography of the alloy it is most profitable first to consider the binary alloys, barium-lead and calcium-lead. The constitution of the latter series of alloys has been investigated by N. Baar⁶ and L. Donski,⁷ and a portion of the thermal equilibrium diagram, adjacent to the lead side, as published in Landolt,⁸ is reproduced in Fig. 3.

Several points in the curves have been checked very closely by determinations made at this laboratory. It appears from the complete diagram that additions of

calcium up to 6 per cent, where the compound Pb_3Ca is formed, raise the melting point rapidly. Other compounds are formed beyond this and the melting point is increased to 1,100 deg. C. The photomicrographs, Figs. 5 and 6, are in accord with this equilibrium diagram. They show crystals of lead-calcium compound Pb_3Ca in a ground-mass of lead. The crystals appear to be rod- or needle-shaped, and at higher magnification the rods are shown to be built up of cubical crystals. (Fig. 10.)

Calcium-lead alloys for experimental purposes were made at this laboratory from pure lead and metallic calcium. The lead is melted in a ladle and heated to about 500 deg. C. A piece of calcium is then held under the molten lead, being scraped meanwhile to remove oxide, etc., and to permit the lead to come in contact with clean metallic calcium. When the calcium dissolves, there is a decided exothermic reaction and more lead in bar form is quickly inserted in the molten metal to cool the alloy and prevent oxidation. In this way alloys containing up to 6 per cent calcium were made up

to be used as base metals in preparing other alloys for further investigations.

In studying the constitution of barium-lead alloys no published data could be found.⁹ An alloy was produced for us at the plant of the United Lead Co. at Keokuk,

Ia., by the electrolytic process from fused barium chloride, using molten lead as cathode. (Table I.) By diluting this with pure lead, alloys of varying compositions were produced for our investigations. Cooling curves were determined both by the differential and the inverse

⁹After our work was completed an abstract appeared in *Chemical Abstracts*, vol. 15, p. 662, describing an investigation of barium-lead alloys first published in *Zeitschrift für Metallkunde*, Oct. 1, 1920 ("The Constitution Diagram of the Alloys of Lead and Barium," by J. Czochralski and E. Rassow). Our work was in fact practically completed before that date, and is corroborated by the results reported in the article.

rate methods. From the results obtained the equilibrium diagram shown in Fig. 4 was derived.

Photomicrographs are in accord with the thermal equilibrium diagram and show a eutectic of lead with a lead-barium compound (presumably Pb_3Ba). From the diagram published in the article referred to,⁹ it appears that an examination was made of an alloy containing as little as 0.14 per cent barium, and that presence of eutectic was found therein. Judging from this, no solid solutions are formed unless with smaller amounts of barium. In the work carried out at this laboratory microscopic examination indicates the presence of eutectic in the alloys containing barium down to at least 0.50 per cent (Figs. 7 and 8). In the thermal study the alloy lowest in barium of which cooling curve was made—namely, 0.70 per cent barium—plainly shows the presence of eutectic. Its structure is not the completely homogeneous solid solution, rather being composed of homogeneous crystallites (either pure lead or solid solution with a very small amount of barium) surrounded at their boundaries by another component, a eutectic. In the alloys containing above $4\frac{1}{2}$ per cent barium and up to 6 per cent barium, coarse rod-like crystals make their appearance in the micrographs, which presumably consist of the compound Pb_3Ba (Fig. 9).

In the ternary calcium-barium-lead alloy, containing slight amounts of other elements (Frary metal), the eutectic forms at a slightly lower temperature than is the case with the binary barium-lead eutectic. That is, from study of the photomicrographs and thermal equilibrium of Frary metal the eutectic is found to be at a temperature of 284 deg. C. instead of 291 deg. C.; otherwise, however, the structure is such as would be expected from a combination of the binary alloys calcium-lead and barium-lead. There are, however, some indications of solid solutions being formed in the alloy up to about 0.2 per cent calcium and 0.4 per cent barium. The structure consists of homogeneous grains of lead, probably containing some calcium and barium in solid solution, surrounded by eutectic of this solid solution with lead-barium compound (Pb_3Ba), together with crystals of lead-calcium compound (Pb_3Ca) embedded in this ground mass of solid solution and eutectic (Fig. 10). The critical points found in thermal study of some of these alloys are given in Table II.

As indicated by Table II, there is a range of tempera-

ture in cooling such an alloy from a molten state, through which freezing of some of its components continues until complete solidification is reached. The binary barium-lead alloys, in the range studied, melt at a lower temperature and have greater apparent fluidity than pure lead. In the binary calcium-lead alloys, the complete solidification point is at the melting point of lead, but the presence of lead-calcium compound gives a somewhat higher complete liquefaction point. In the ternary alloy the latter point is above the melting point of lead, while the solidification point is lower than that of lead. This range of temperature through which solidification takes place in Frary metal is no greater, however, than the range of temperature through which most tin base bearing metals are partly fluid and partly solid.

The practical pouring temperature of any metal should, of course, be well above its complete liquefaction point, the best temperature logically depending upon the size, shape and temperature of the mold into which it is

to be cast. Other lead base alloys of the class of bearing metals and type metals melt at a comparatively low temperature, corresponding closely to the melting point of antimony-lead eutectic, and there is in most of these alloys only a short range of temperature between their complete solidification and liquefaction points; whereas Frary metal begins to melt at a temperature closer to the melting point of lead itself and corresponds in its comparatively wide melting range of temperature more nearly to tin base babbitt metals. In remelting and pouring into castings, therefore, it is necessary to use a higher temperature than with lead base alloys containing antimony.

Combination with oxygen in general takes place the more readily the higher the temperature. Frary metal does not oxidize or form dross to any greater extent than lead itself or other similar alloys at the temperature in question. In remelting ingots or other cast shapes of any metal or alloy, to avoid oxidation or drossing, the crucible, pot or ladle should, when practicable, be first heated to a temperature above the melting point of the metal, a small part of it first melted, and then the remainder added a little at a time at the rate at which it melts. With some alloys there may be

FIGS. 11, 12 AND 13. HARD CRYSTALS IN RELIEF ON POLISHED BEARING METALS. $\times 50$

a tendency under certain conditions for one element to oxidize more readily than another. However, Frary metal, as now produced, shows no tendency toward loss of its constituent elements by oxidation, when remelted by ordinary good practice. Alloys containing only barium and lead, on remelting, lose barium by oxidation. The calcium-lead alloys as made in this laboratory with the purchased metallic calcium, analysis of which is shown in Table II, do not act in this way, although calcium itself oxidizes very readily in the atmosphere. The surface of the molten metal has a very bright silvery appearance, free from oxide. The cause for this may be in the presence, as an impurity in the metallic calcium used, of a very slight amount of some other element. The absence of any tendency in Frary metal to lose its constituent elements by oxidation is probably due to a similar protective or deoxidizing action. The addition of small amounts of some metallic elements has proved beneficial, whereas the presence of slight amounts of other elements is harmful and must be avoided.

PECULIAR PROPERTIES

Cast specimens of some of the alloys have shown a remarkable increase in hardness and strength upon aging. The cause of this change which takes place in the solid metal may be similar to the theory advanced for a somewhat like hardening which takes place in duralumin.¹⁰ This is more pronounced with the alloys containing the lower percentages of calcium and barium. The period over which the change in hardness takes place is shortened by the addition of some other elements.

The hardness of the alloy, when in certain forms, can be increased by heat-treatment. In this respect also its behavior is similar to that of duralumin.

Pure lead, as is well known, emits a very dull sound when struck, while these alloys are quite remarkably resonant. This appears to be largely due to the presence of barium, since we have shown that cast lead containing only 0.08 per cent barium is quite highly sonorous, emitting a clear bell-like sound on being struck.

REQUISITES OF BEARING METAL

Frary metal, as described above, has a very large field of usefulness, especially as an excellent bearing metal. It has been found valuable for many purposes where strength and hardness is required, and can be readily cast in brass or iron molds, or made into die castings. It has also found use in the form of extruded pipe, tubing and rod; rolled sheets; and in swaged forms. As a bearing metal it has strength without brittleness, and also remarkable anti-frictional properties, while retaining largely the characteristics of lead in respect to plasticity (malleability, unctuousness).

It is generally recognized that the structure which renders an alloy suitable for use as a bearing metal consists of a crystalline component embedded in a plastic ground mass. The purpose of this desired structure is to give sufficient hardness to the bearing metal to enable it to resist the required pressure and at the same time impart to it the quality of plasticity, so that the bearing will adapt itself to any irregularities in fit and alignment. The metal should have the greatest hardness

compatible with the necessary plasticity; this hardness, however, being much less than the hardness of the shaft so that in case of injury the latter will not be scored, but the bearing metal itself will suffer. A metal having these properties of hardness combined with plasticity will have good anti-frictional qualities, since, as generally thought of, this term probably involves a low coefficient of friction and also so-called unctuousness. The former is actually the lower with the greater hardness, and the latter, used in this connection, may be simply the property of plasticity.

It appears from photomicrographs and from the working qualities of Frary metal that its structural components have all of these characteristics in a marked degree. Figs. 12 and 13 show photomicrographs of

Frary metal, and a tin base babbitt metal prepared under the same conditions. These indicate that the structure of Frary metal is very similar to that of high-grade tin base bearing metals, and the similarity is even more notable when compared with the somewhat different structure of other lead base bearing metals. In Frary metal the presence of lead (or solid solution of lead with small amounts of calcium and barium) in the ground mass is undoubtedly partly the cause of the high degree of plasticity which is characteristic of the metal, and it is evidently distributed throughout the alloy in such a way as to result in no sacrifice of hardness.

In actual service bearings attain a temperature above normal, in many cases due to faulty lubrication or other causes. Their value in service then depends upon their properties at such temperature. Metals in general decrease in hardness and strength with rise in temperature to zero at the melting points. The decrease appears in general to be approximately a linear function with change of temperature; therefore, at elevated temperatures, metals having low initial solidification points are at a disadvantage in this respect, as shown by the figures in Table V.

Discovery of New Nitrate Lands in Chile

The Chilean Government has sent a mining engineer to Iquique to investigate a report of the discovery of a new nitrate zone, reports Consul Brett in *Commerce Reports*. A prospector claims he has found nitrate beds underlying a district of about 2,000 sq.km., where no nitrate was previously known to exist. The region is in the Province of Tarapaca, and it is said that the results of forty blasts, put in at distances of from 3 to 4 km. apart, show that beds of caliche from 2 to 3 ft. thick containing from 20 to 40 per cent of nitrate of soda underlie the region at a depth of 11 ft. below the surface.

¹⁰"The Heat-Treatment of Duralumin," by P. D. Merica, R. C. Waltenberg and H. Scott. A. I. M. E., June 1919. See also "Slip Interference Theory of the Hardening of Metals," by Zay Jeffries and R. S. Archer, CHEM. & MET. ENG., vol. 24, p. 1057 (June 15, 1921).

Solvents for Cellulose Esters*

Review of the Principal Solvents for Nitrocellulose and Cellulose Acetate—Development of a Pure Anhydrous Ethyl Acetate Which Is Known Commercially as Acetic Ether and Which Appears to Possess Unusual Solvent Properties

BY H. F. WILLKIE

Research Laboratory, U. S. Industrial Alcohol Co.

THERE are two general types of solvents for cellulose esters. The first type are the solid solvents, which act upon the nitrocellulose whereby it loses all structural form and together with the solvent passes into a homogeneous plastic mass. The combination of such a solvent with the cellulose ester is brought about through the application of heat or pressure, by the addition of a liquid solvent, or by a combination of these methods. The homogeneous plastic mass once formed may be worked under influence of heat and pressure into any desired shape. Examples of this class of solvents, which are also known as latent solvents, are camphor, acetanilide and triphenyl phosphate.

The second general class of solvents are the direct or liquid solvents, which dissolve directly without such aid as heat or pressure. These solvents first act upon the cellulose esters to form a colloidal mass, which, upon the addition of further solvent, becomes a free flowing solution which may be indefinitely diluted with the same solvent. These solvents produce solutions which evaporate to leave clear films of the cellulose esters. The solutions are used as lacquers and protective coatings for wood, metal and other products; as a covering for cloth in the manufacture of artificial leather, and in the production of photographic films. When once dry these films can be redissolved by a direct solvent, but cannot be molded under the influence of heat or pressure unless a latent solvent such as camphor be present. Consequently for many purposes combinations of direct and latent solvents are used. Some of the more generally known direct solvents are amyl acetate, acetone and ethyl and methyl acetates.

Because of the relative high cost of high-grade solvents such as amyl acetate it is desirable to dilute them with non-solvents or with other cheaper solvents which alone would not give satisfactory results. These diluents may add some useful property to the mixture or may merely act as thinners. Examples of non-solvents which often impart valuable properties to solutions are the alcohols (ethyl, methyl, propyl), fusel oil, benzine and benzene. Included with the direct solvents are the mixtures of solvents with thinners and other solvent mixtures made of combinations of two liquids which separately are non-solvents but together from a solvent, such as alcohol and ether.

EFFECTS OF WATER IN SOLVENT MIXTURES

To the list of non-solvents should be added water. This non-solvent has given rise to a great deal of trouble in the development of the cellulose-ester industry, especially from the solvent standpoint. It is a precipitant of cellulose ester, and a solution of a cel-

lulose ester in a hygroscopic solvent will take up moisture to the point of precipitation. A solution of a cellulose ester in a mixture containing a solvent and non-solvent will not evaporate to form a clear film, but will precipitate whenever during the course of evaporation of the solvent the unevaporated portion is no longer a mixture in which the cellulose ester is soluble. This rule, of course, applies to water. Consequently, the use of a hygroscopic solvent with a boiling point below 100 deg. C. will often result in precipitation, or film blushing, as it is known, unless great precaution is exerted to prevent absorption of water.

A solution in any solvent which evaporates rapidly enough to cause an appreciable lowering of the temperature of the surrounding atmosphere and thereby resulting in a precipitation of moisture upon the evaporating solution is apt to suffer from this same trouble, especially if the solvent is also hygroscopic. Because of this difficulty a high boiling point, at least above 100 deg. C., has been considered one of the prime requisites of a good solvent. The quality of a lacquer, imitation leather or photographic film depends first of all upon the use of a solvent or solvent mixture which will evaporate in such a manner as to eliminate water and thereby leave a clear strong homogeneous film free from precipitation or blush.

SOME PROPERTIES OF AMYL ACETATE

Since 1882 amyl acetate has been the most important solvent for cellulose nitrate and has enjoyed extreme popularity due to its many important properties, among which are its high boiling point, low solubility in water, absence of hygroscopicity, its ability to stand high dilution with non-solvents (especially with benzene in the preparation of lacquers) and its property of producing smooth films of luster and high tensile strength. On the other hand, amyl acetate has low solvent power in comparison with acetone and ethyl acetate. Its variability of composition and, above all, its rapidly increasing scarcity, which has been accompanied by a corresponding rise in price, are factors which have tended to limit its use as a solvent for cellulose esters.

In the past few years there has been a tremendous growth of the industries based upon cellulose-ester solutions. The almost universal use of automobiles has increased the demand for artificial leather, the airplane has brought in an increased demand for dopes or lacquers, and the motion picture industry consumes tremendous quantities of films. Together with increased use of these products has come the rapidly decreasing supply of the industry's most dependable solvent and the necessity of, and demand for, new solvents or solvent mixtures. Out of this need first came greater dilution of the amyl-acetate solvents with non-solvents—the introduction of varying quantities of methyl ace-

*A paper read before the Section of Cellulose Chemistry at New York City on Sept. 7, 1921, and published by permission of the American Chemical Society.

tate, which could be obtained in an anhydrous condition but which soon became prohibitive in price—and later the rather general introduction of ethyl-acetate mixtures consisting of ethyl acetate and alcohol and ethyl acetate and benzene, with varying amounts of water dependent upon the source and method of manufacture of the ethyl acetate. These solvent mixtures are used together with a quantity of high boiling solvent, such as amyl acetate, sufficient to produce a solution which will evaporate without fogging. However, these solvent mixtures do not and cannot take the place of amyl acetate, and the demand for such a solvent is not satisfied by them.

PRODUCTION OF ANHYDROUS ETHYL ACETATE

This unsatisfied demand has led to experimentation with ethyl acetate, which has long been known to be a powerful solvent for nitrocellulose, but with which great difficulties had been encountered in attempting to produce it as an anhydrous product. However, this work has resulted in the development of successful and economical processes for the production of anhydrous ethyl acetate free from both alcohol and water and of many other anhydrous esters and solvents.

Heretofore but little has been known regarding ethyl acetate which is free from water and alcohol. However, acetic ether,¹ as this product is designated in this paper, promises to take the place to a great extent of amyl acetate and to extend greatly the field of cellulose ester solutions. Since acetic ether is produced from acetic acid and alcohol, the possible supply is practically unlimited. Furthermore, it should not increase materially in price, but naturally it should decrease as its manufacture on a large scale becomes justified through its increased use.

Acetic ether has suffered and still suffers from adverse criticism, due to information based on experiments with impure products and lack of knowledge of the behavior of the pure anhydrous preparation. References have been made repeatedly in the literature to the tendency of acetic ether to take on a strong acid reaction on standing.² Pure acetic ether as such or pure acetic ether diluted with 95 per cent alcohol does not show any indication of this objectionable property. Samples of acetic ether, and acetic ether and alcohol, after standing for 1 to 2 years have shown only a slight trace of acidity or even complete freedom from the same. After eighteen months' time four representative samples showed: 0.009 per cent, 0.024 per cent, 0.017 per cent and 0.009 per cent of free acetic acid. Acetic ether is stable even when treated with hot water.

Iron drums in which acetic ether had been stored for months have shown no evidence of corrosion, nor was the ester itself discolored. Chemical tests of acetic ether show that the supposed acid-developing tendency cannot be too strongly denied.

Another objection raised to acetic ether and which is found frequently in the literature is its alleged hygroscopicity.³ It is known, however, that acetic ether is not hygroscopic, but on the other hand takes up moisture very slowly. High-grade acetic ether such as produced by the process previously referred to, after standing in a storage tank with a loose cover for a month, showed no action on metallic sodium when the latter was placed

in it. Acetic ether stored in drums for 6 months gave the same result.

A third commonly repeated objection to acetic ether is its volatility or low boiling point (77 deg. C.).

Having discussed briefly the more common objections to acetic ether, some of its properties will now be considered. It is a colorless, limpid, pleasant smelling fluid, entirely free from disagreeable and poisonous fumes. It evaporates without a visible or detectable residue. Being a pure compound, it evaporates at a uniform rate. Acetic ether is unaffected by light or air. Samples stored for months in bottles or exposed to the air in storage tanks have shown no signs of deterioration. It is a powerful solvent for nitrocellulose and is a good solvent for the more soluble forms of cellulose acetate.

TESTS WITH NITROCELLULOSE

In this connection the description of a series of experiments which were carried on to determine the nature of acetic ether and acetic ether-ethyl alcohol mixtures as solvents for nitrocellulose might be of interest. Samples of nitrocellulose were obtained from the Hercules Powder Co. and showed the analyses given in Table I.

TABLE I. PROXIMATE ANALYSES OF NITROCELLULOSE SAMPLES

Description	Nitrogen	(In per cent)		Ash	Moisture
		Insoluble in Ether and Alcohol	Insoluble in Acetone		
"L," low viscosity.....	12.00	0.40	0.15	0.14	27.9
"P,"	11.14	3.25	0.26	0.12	38.1
"M," medium viscosity..	12.13	0.08	0.15	0.13	29.2
"H," high viscosity.....	12.06	0.10	0.08	0.14	28.0
"V.H.," very high viscosity.....	12.18	2.15	0.30	0.20	32.3

These samples were wet with alcohol when received and were all dried at about 50 deg. C. before using. They are designated by the letters "L" "P" "M" "H" and "V.H." respectively.

The alcohol used was 95 per cent ethyl alcohol containing $\frac{1}{2}$ per cent of benzene. The acetic ether and alcohol were mixed so as to give mixtures containing 10 per cent of acetic ether and 90 per cent of alcohol, 20 per cent of acetic ether and 80 per cent alcohol and so on, advancing by tens to the pure acetic ether. These mixtures are designated as "10 per cent," "20 per cent," "30 per cent," . . . "100 per cent" acetic ether.

To weighed samples of the nitrocellulose in large test-tubes were added measured amounts of the different ester mixtures; a separate tube was set up for each solvent with each sample of nitrocellulose. In each case slightly less of the ester mixture was added than had been found necessary for complete gelatinization of the nitrocellulose.

The tubes were well stoppered and were allowed to stand for 24 hours, when more ester was added in each case. This was repeated until just enough solvent had been used in each case to dissolve the nitrocellulose, while the addition of more solvent merely rendered the mixture fluid.

The solubilities expressed as ounces of nitrocellulose per gallon of solvent were found to be as shown in Table II and the curves prepared from these data are shown in Fig. 1.

From these experiments it will be seen that acetic ether has a high solvent power for the various samples of nitrocellulose, dissolving from 11.2 to 30 oz. per gallon of solvent. Further, it may be noted that the high dilutions possible with 95 per cent alcohol is accom-

¹It is appreciated that this does not conform with exact chemical nomenclature, but the term is used here because of its commercial significance. In the trade "ethyl acetate" refers to the 85 per cent material, and "acetic ether" is used to designate the 99 to 100 per cent ethyl acetate.

²"Nitro-Cellulose Industry," by E. C. Worden, vol. 1, pp. 230 and 434.

³"Nitro-Cellulose Industry," by E. C. Worden, vol. 1, p. 434.

TABLE II. SOLUBILITIES OF NITROCELLULOSE SAMPLES IN VARIOUS MIXTURES OF ACETIC ETHER AND ALCOHOL.

Solvent	Nitrocellulose Samples				
	L	P	M	H	V.H.
10 per cent acetic ether.....	30.6	27.8	26.5	23.6	11.7
20 per cent acetic ether.....	36.7	28.7	29.0	24.5	12.2
30 per cent acetic ether.....	37.2	29.4	29.7	25.7	13.0
40 per cent acetic ether.....	38.0	30.0	30.0	25.7	13.5
50 per cent acetic ether.....	37.7	29.4	28.7	25.7	13.2
60 per cent acetic ether.....	37.2	28.9	28.4	25.3	13.0
70 per cent acetic ether.....	35.8	28.5	28.1	24.6	12.8
80 per cent acetic ether.....	33.5	26.8	27.3	24.0	12.2
90 per cent acetic ether.....	29.7	23.4	23.5	23.0	11.2
100 per cent acetic ether.....					

panied by an increase rather than decrease in the solvent power of the mixture.

A similar set of experiments showed the possibility of diluting the acetic ether with benzene to the point of a mixture of 70 per cent of benzene and 30 per cent of acetic ether. Although solvent for the various nitrocelluloses, the dilution with benzene beyond a 50-50 mixture reduced the solvent power appreciably.

FIG. 1. SOLUBILITY OF NITROCELLULOSE IN ACETIC ETHER-ETHYL ALCOHOL MIXTURES

Curves showing the relative viscosities of 5- and 10-oz. solutions of nitrocellulose in these solvent mixtures are shown in Figs. 2 and 3.

The solvent properties of acetic ether for cellulose acetate were shown by experiments with three different lots of cellulose acetate obtained from the Eastman Kodak Co. over a period of 3 years. All dissolved in anhydrous acetic ether to the extent of about 25 oz. to 1 gal. of solvent and gave good workable solutions of 10-oz. strength from which films were produced. Another sample of cellulose acetate was found to be soluble to the extent of 20 oz. per gallon. Later a sample of salvage cellulose acetate proved to be insoluble in acetic ether, but experiments demonstrated that this sample was also insoluble in other cellulose acetate solvents.

Besides being a powerful solvent for the cellulose esters, acetic ether, alone and together with small percentages of alcohol or water, or diluted by with as much as 50 per cent of chemically pure benzene, will produce solutions leaving satisfactory films upon evaporation.

Clear, strong films were produced by permitting the following solutions to evaporate under the ordinary atmospheric conditions of the laboratory: Solutions of various samples of nitrocellulose in acetic ether, acetic ether diluted with 5 per cent of 95 per cent alcohol, acetic ether wet with 2 per cent water, and acetic ether diluted with an equal volume of c.p. benzene; a solution of cellulose acetate in acetic ether, and one of half cellulose acetate and half cellulose nitrate in acetic ether.

Acetic ether is an example of a low boiling solvent

FIG. 2. RELATIVE VISCOSITIES OF 5-OZ. NITROCELLULOSE SOLUTIONS

(b.p. 77 deg. C.) giving a result which in the past has been considered possible only from a non-hydrosopic solvent boiling above 100 deg. C., such as amyl acetate. The effect of water upon the low boiling solvents and upon hydrosopic solvents has already been discussed.

The explanation of this unusual and important behavior of acetic ether depends chiefly upon its characteristic property of forming constant boiling mixtures with water. Among the constant boiling mixtures of acetic ether with other liquids are the following:

With Water. Acetic ether 91.4 per cent, water 8.6 per cent. Boiling point, 70.45 deg. C.

FIG. 3. RELATIVE VISCOSITIES OF 10-OZ. NITROCELLULOSE SOLUTIONS

With Alcohol. Acetic ether 69.4 per cent, alcohol 30.6 per cent. Boiling point, 71.8 deg. C.

With Alcohol and Water. Acetic ether 83.2 per cent, alcohol 9.0 per cent, water 7.8 per cent. Boiling point, 70.3 deg. C.

The relative low boiling point of acetic ether becomes a decided advantage. It makes possible rapid work. Further, by control of the temperature of evaporation and other atmospheric conditions such as concentration of evaporating solvent any desired rate of evaporation may be maintained.

German Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

ESSEN, Nov. 28, 1921.

JUDGING from the commercial reports of the principal German newspapers, opinion as to the prospects and future of the German chemical industries is still divided. Pessimists still reckon on the possibility of France demanding that the greater part of the chemical works be dismantled, on the ground that in case of a new war they could be able to manufacture war gases. On the other hand, the stock exchange, which at all times is a better barometer for the course of future events, does not seem to share such a gloomy view.

While in normal times, and even until recently, the market for industrial debentures varied generally only between 95 and 100 per cent, the recent rush to invest money caused the price for these debentures to reach a figure never known before, this increase varying in proportion with the confidence the public has in the future prospects of each individual undertaking. The $4\frac{1}{2}$ per cent debentures of the undertakings united in the great dye trust have beaten all previous records. The obligations of the Badische Anilin und Soda-Fabrik and the Elberfelder Farbenfabriken vorm. Friedr. Bayer (yielding $4\frac{1}{2}$ per cent interest in paper marks) reached their highest bid at 180 per cent, a price which has never previously been known to be paid in Germany for industrial debentures of any kind.

CHEMICAL MARKETS

The situation in all branches can be considered favorable, although the intensity of buying has somewhat relaxed this month, but everything offered is readily sold. Prices are increasing continually and in consequence contracts cannot be placed at fixed prices. As the prices have, however, reached an exceptional and one is very much inclined to say a phantastic level, buyers are somewhat more careful, with the result that the situation has begun to ease a little. In consequence the available quantities of chemicals offered in the open market were much smaller than usual and were readily disposed of. As examples may be mentioned borax, which had reached the exorbitant figure of 45 marks per kilogram and has since dropped to 37, with the result that it has disappeared from the market entirely; mercury is much in demand, but only very small quantities are to be had, these changing hands at 300 marks per kilogram exclusive of bottles; sulphur in lumps reached 6.50 to 6.75 marks per kilogram; sulphuric acid as supplied through the German ammonia syndicate to the byproduct coking plants has also been increased in price—to 83 marks per 100 kg. from Nov. 1.

TAR PRODUCTS

The market in anthracene is very quiet due to the fact that the large dye works accumulated thousands of tons during the war when it was very cheap and are thus fully supplied with this material for a number of years to come. The comparatively cheap price paid for anthracene during the war is explained by the fact that the manufacture of oils for fuel and lubricating purposes was of primary importance and anthracene was then considered merely a byproduct.

Benzene, toluene and xylene have been increased in price during October, but in spite of these increases these products are still sold at a figure much below the rates prevailing on the world markets. The rapidly

jumping prices for imported gasoline have again increased, with the result that the demand for benzene exceeds the available quantities by far.

To relieve the acute shortage of liquid fuel the benzene syndicate, which is under government control, has recently introduced a new standard motor fuel called "tetralitbenzol." It consists of two parts by weight of motor benzene, one part motor tetraline and one part of 95 per cent alcohol. This fuel is introduced and distributed now on a considerable scale and has proved very serviceable for motor cars or any other internal combustion motors. A great number of mixing plants have been erected all over Germany so as to insure an even distribution all over the country. The new fuel has been well received by the consumers and by its use the amount of benzene available for home consumption is increased by 4,000 tons per month through this addition of tetraline and alcohol, so that Germany is practically independent of foreign supplies of motor fuel.

DYES

The turnover in dyes is somewhat quieter and in the export trade the Swiss competition is keenly felt. The American and English competition is also a disturbing factor. Trade with Italy is much impaired by the peace treaty with that country which makes compulsory the supply by Germany of certain quantities of dyes and chemicals.

On the whole the chemical industry is suffering acutely from the general scarcity and inferior quality of fuel. Apart from this impediment in production, the works are sold out for several months to come, so that today only goods for supply in January or February can be promised. Owing to the shortage of railway cars, even wholesale dealers cannot supply promptly and for many chemicals no offer at all can be had.

Surface Defects on Brass Sheet

H. A. Hays read a paper on "The Rolling of 70:30 Brass" before the Birmingham (England) Metallurgical Society in November, 1921. As reported by the *Iron and Coal Trades Review*, he noted that the surface defects chiefly met with in brass strip and sheet could be divided into three main classes: (1) Spilly areas, (2) scratches, rolled-in mill scale or dirt, (3) stains. The first named was the most serious and was too frequently met with. Spilly areas were due to bad pouring, which caused splashing of partly solidified metal on the surface of the ingot mold, cracks and serious porosity of the ingot mold and fragments of sand, metal, etc., mixed in with the mold facing. The steelworks practice of machining blooms all over before rolling into strips could be advantageously adopted.

Mechanical defects were altogether too frequent. The rolling-in of mill scale and dirt could be avoided by adopting closed muffles for all heating operations and the keeping the floor of the rolling mill clean, and, as far as possible, keeping the material off the floor. Continental manufacturers are able to produce excellent finish by the use of steel rolls, the use of which in England is limited.

Recent work by the Non-Ferrous Research Association indicated that the removal of grease from the material before annealing greatly helped in preventing staining. Insufficient cleaning and pickling or the presence of chlorides in the wash water resulted in the material becoming badly stained after being left standing for some time.

Synopsis of Recent Chemical & Metallurgical Literature

British Steel-Works Practice.—R. H. Archer Coulson, president of the Cleveland (England) Institution of Engineers, delivered an address¹ before that body in which he outlined the changes in their industry which might possibly be used to offset high cost of labor and fuel. Given a well-designed plant, built with the idea of saving fuel, the main determining factor of success is *reliability* of the various independent operating units. Material handling should be simple and continuous; avoid intricate machines which will require heavy attendance and upkeep costs. Again, material may get into a department efficiently, but get out wastefully. The speaker feels that storage battery locomotives will be a great time and money saver. Low-ash coke, pure limestone and high-grade ore should be insisted upon; poor chemical and physical properties of coke are especially expensive at any price. Much yet remains to be known about the factors which promote combustibility—that prime requisite of coke as a blast-furnace fuel. Irregularities in practice should be avoided if at all possible—a furnace running well on fine ore will show distress if given several charges of lumpy ore. Pure fluxes are of great importance in the open-hearth furnace, not so much from the increased tonnage, but the loss of iron in the slag. Silica and magnesite brick are not so good as before the war. Gas houses should operate, not to make the richest gas, but the gas which burns with the highest temperature. Waste-heat boilers are to be recommended. After all, the most important factor is the weight of ingot required to produce a ton of finished material. Given sound ingots, good heating practice is of great importance, in keeping this weight down and in reducing power and repair bills. Continuous operation is essential to economy in every department, even though workmen are paid by tonnage rates. Reliable, simple, stout, and if possible automatic electrical equipment will cut down incidental and exasperating delays remarkably. Cleanliness and order will work to the same ends. Finally, but perhaps most important, every member of the staff and every workman should have a desire to do his best, to have “the pride of craft.”

Water Japan Installations.—The November issue of the *General Electric Review* contains an article by Wheeler P. Davey and P. Dunning describing several installations at the General Electric Co.'s plants using the water japan developed in the research laboratories of the company. This water japan is an emulsion of an asphalt oil base in water. It may be applied by two methods: the electric dip, in which the articles to be coated are charged positively; the hot dip, in which the articles are preheated before dipping in the japan. (See CHEM. & MET. ENG., May 19, 1920.)

Two small installations at the Schenectady works are described briefly, followed by a discussion the installation at the Sprague works, which is the first to use water japan on a large scale. The latter consists of three electrically heated conveyor ovens of the vertical intermittent type. Two of these have a maximum capacity of 2 tons per charge; the third, 3 tons per charge. The dip tanks, placed in a pit below the floor level, are provided with cooling coils and air jets so arranged that the temperature of the japan is always below 70 deg. F., even without the use of a circulating pump. Each tank holds about 900 gal. of japan. This provides enough heat capacity in the japan itself to prevent undue temperature rise during dipping.

Articles to be japanned are hung from hooks on the bars of the conveyor, if large, or placed in baskets, if small. After preheating to about 500 deg. F., the articles pass through the dip tanks at a speed of not less than 6 in. per second, and then back to the oven, where the japan is baked for 20 to 30 minutes. When operating on a load

of 4,000 lb., the efficiency of the 2-ton ovens for preheating plus baking is 11 lb. per kw.-hr. With smaller loads the efficiency is, of course, less. For instance, if the load is decreased to 1,800 lb., the efficiency is only 6 lb. per kw.-hr. The 3-ton oven has never been loaded to its maximum capacity, so that actual data are not available, but it is estimated that if it were so loaded its efficiency would be 14 lb. per kw.-hr. These figures compare favorably with those obtained with box-type or other intermittent ovens.

The relative freedom from drip, which is a characteristic of water japan, prevents material on one bar from being marred by japan dropping from the next higher bar and also prevents prohibitive scarring of the work which is dipped in baskets. Data taken on metal totaling several thousand square feet in area show a coverage of a little more than 200 sq.ft. per gal. of water japan. In spite of the large amount of metal that is japanned daily by the ovens at the Sprague works, it is not necessary to measure the concentration of the japan oftener than once a week. Since the solvent (water) is relatively non-volatile, there is no need for the daily addition of “thinner,” so that the low initial cost of water japan is further supplemented by the saving in the cost of thinner. These advantages are nevertheless of but supplementary importance compared with the main purpose for which the water japan was developed—the absolute elimination of fire risk.

Contribution to the Study of Titanium.—The July-August, 1921, issue of *Annales de Chimie* contains the results of the research work on titanium made by Maurice Billy at the Institut de Chimie Appliquée (pp. 5 to 54). His study consisted in obtaining the raw materials for the preparation of pure metallic titanium, gaseous and solid hydrates, oxides (TiO , Ti_2O_3 , Ti_2O_4 , Ti_2O_5), crystallized persalts, complex double sulphates and the determination of the degree of oxidation of the compounds obtained in acid solution in the presence of hydrogen peroxide.

He obtained the raw material used in his study by mixing 1 part of commercial titanium anhydride with 6 parts of sugar and transforming this into chloride by calcining, pulverizing, heating to 1,000-1,200 deg. C. in a current of dry chlorine in a porcelain tube. The impurities of the resulting chloride were separated by an agitation with sodium amalgam and a fractional distillation at 135-137 deg. C. under normal pressure.

After passing in review the different methods employed in the preparation of metallic titanium he describes in detail the method he employed, based on the reaction

and gives the schematic arrangement of the apparatus used (p.14). Qualitative and quantitative tests have shown no trace of impurities.

Nascent titanium absorbs hydrogen, giving a black mass, which is titanium hydride. He describes the method of preparation and the apparatus used (p. 21).

The only titanium oxide which can be obtained easily in a perfectly pure state is TiO_2 and this served for the preparation of the other oxides by reduction with hydrogen or by the action of metals having a greater affinity for oxygen. After describing in detail the preparation of pure TiO_2 he passes in review the methods formerly used for the reduction by hydrogen and then gives his method with the schematic arrangement of the apparatus used (p. 27). Similarly he passes in review the methods formerly used for the reduction of TiO_2 , especially by magnesium and zinc, and gives his procedure and came to the result that the most convenient metal is titanium and that the mixture TiO_2 -Ti heated in a specially constructed furnace shown schematically on pp. 39 and 41 he was able to obtain all the oxides according to the degree of heating. Thus:

Between 700–800 deg. C. he obtained a blue oxide, Ti_2O_3 .
Between 900–1,000 deg. C. he obtained a violet oxide, Ti_2O_3 .
Between 1,100–1,200 deg. C. he obtained a black oxide, Ti_2O_3 .
Between 1,400–1,500 deg. C. he obtained a brown oxide, TiO .

He then studied the preparation of persalts and states that he has succeeded in preparing crystallized sulphates of titanium peroxide. He concludes with the statement that all the salts of titanium are not salts of TiO_2 , as given by previous authors, but salts of $\text{Ti}_2\text{O}_3 \cdot \text{H}_2\text{O}$.

¹Reported in *Iron and Coal Review*, Nov. 11, 1921.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Production of Acetaldehyde.—A process for the catalytic production of aldehydes, with particular reference to the manufacture of acetaldehyde from ethyl alcohol, is the subject of a patent granted to Arthur A. Backhaus of Baltimore and Fred B. Arentz of Curtis Bay, Md., assignors to the U. S. Industrial Alcohol Co. To carry out the process, the alcohol is introduced in the still 1 (see figure), which is heated by the steam jacket 2. The alcohol vapors are conveyed to the preheater 4, where they are heated to about 300 deg. C. by means of the oil jacket 4a. The vapors enter the catalyzer 5, which is filled with pumice stone, unglazed porcelain, charcoal or a similar granular porous

material upon which has been deposited the finely divided catalyzer metal. The catalyst used is copper, nickel, chromium or iron. The oil jacket 7 maintains the vapors in the catalyzer at approximately 300 deg. C. throughout the length of the tube, and a large percentage of the alcohol is decomposed to form acetaldehyde and hydrogen. The vapors passing out of the catalyzer are conducted through the condenser 11, maintained at a temperature of 20 to 30 deg. C., where any alcohol vapors present are condensed and are collected in the receiver 14. The acetaldehyde and the hydrogen pass out of the receiver and are conducted to the compressor 16a, where the gases are compressed to approximately 60 lb. per sq.in. The compressed gases then pass through the condenser 17, maintained at a temperature of 10 to 20 deg. C., where the acetaldehyde is condensed and collected in the receiver 20. In case the compressor 16a is not used, the temperature in the condenser 17 is kept at about 0 deg. C. by means of a brine bath. The hydrogen is conveyed away from the receiver 20 by the pipe 21, through the relief valve 22. The hydrogen may be collected in any suitable manner. (1,388,841; Aug. 30, 1921.)

Purifying Fuel Gases.—Charles J. Ramsburg of Pittsburgh, Pa., assignor to the Koppers Co., has obtained a patent for purifying fuel gases by a process in which the obnoxious constituents such as the sulphur compounds are removed from the gas through absorption in a water solution of sodium carbonate or a similar alkaline salt. It is common practice to pass the gases through boxes filled with iron oxide, but these boxes have to be cleaned frequently and replenished and consequently are expensive to maintain. This invention claims to reduce the quantity of iron oxide to a minimum inasmuch as the purification removes substantially all of the sulphur compounds from the

gas before it passes into the iron-oxide boxes on its way to the mains. An efficient aeration process for regenerating the sodium carbonate solution after it has absorbed the hydrogen disulphide is also provided. This causes the purifying agent to give up its sulphur, thereby permitting a constant reflux of the sodium carbonate solution back to the process. The features of the process which relate to the principle of absorption by the alkaline solution and its regeneration are the invention of David L. Jacobson of Jersey City, N. J., and are covered by patent 1,390,037, which is also assigned to the Koppers Co. (1,389,980; Sept. 6, 1921.)

A New Detonator.—When finely pulverized cyanure chloride is introduced into an aqueous solution of sodium azide, there is obtained a new organic compound, cyanure triazide, which corresponds to the formula C_3N_{12} . Pure cyanure triazide consists of colorless crystals melting at 94 deg. C., is not volatile, but is saponified slowly by hot water, and explodes when subjected to concussion or when heated to 170 deg. C. It is particularly adapted for use as a priming agent as a substitute for mercury fulminate, lead azide or silver azide. In comparison with these priming agents, its inventor claims the following advantages:

(1) It is not poisonous in contradistinction to fulminating mercury and lead azide.

(2) It is not sensitive—that is to say not affected by moisture in contradistinction to fulminating mercury.

(3) It is resistant to and not changed by light in contradistinction to lead azide and to silver azide.

(4) There is no danger of reaction with a metal of the material of the detonator casing or capsule shell, as is the case with lead azide.

(5) It is fusible and its fusion point (94 deg. C.) is so low that the product, melted by a single heating on water or steam bath, can be poured without danger in the capsule shell. It solidifies therein after cooling and shows the density (specific weight) of 1.5.

(1,390,378; Erwin Ott of Basel, Switzerland, assignor to Dr. Edwin Hanton Faust of Basel, Switzerland, Sept. 13, 1921.)

Catalytic Oxidation With Silica Gel.—A patent has been granted to Dr. Ralph H. McKee of New York for the process of oxidizing certain gases in which hydrated silica gel is used as a catalyst. The method is shown to be particularly applicable to the oxidation of nitric oxide to nitrogen peroxide such as is required in the production of nitric acid. In one form of the process the gas stream flows through a series of chambers in which it is alternately exposed first to the action of silica gel and then to the action of water or dilute nitric acid. (1,391,332; Sept. 20, 1921.)

Book Reviews

ORGANIC COMPOUNDS OF MERCURY. by Prof. Frank C. Whitmore of the Northwestern University. 394 pp. New York: The Chemical Catalogue Co. Price, \$4.50.

Probably very few organic chemists, whose chief interests lie in other fields, realize the rich variety and volume of work which has been done in the investigation of the organic compounds of mercury. This monograph by Prof. Whitmore has been "arranged to serve both the general chemist, who wishes to get a conception of what has been done in the field as a whole, and the specialist, who wishes to find out quickly what has been done in any particular portion of the field."

The reviewer is of the former class and from his point of view Prof. Whitmore has succeeded in achieving his purpose. The subject matter is well condensed, but nevertheless has a readable quality which is frequently lacking in mechanically compiled volumes. The omission of practically all detailed experimental material contributes to the readability of the volume. A very large number of literature references are given throughout the text and a bibliographical appendix includes a special list of patents on

organic mercury compounds. The subject index is unusually complete and has evidently been compiled with great care. A monograph which shows such evidence of careful preparation as the present volume naturally inspires the reader with a feeling of confidence. Prof. Whitmore's own experience in this field has enabled him to treat certain subjects very critically, and the present volume is happily not such as are more or less mechanically compiled by persons who have not been actively engaged in original research in the subjects of which they write.

The monograph is confined almost entirely to the true organic mercury compounds in which mercury is attached directly to carbon. No attempt has been made to include biological and pharmacological studies, on account of lack of space and "because of the unsatisfactory condition of the literature of this phase of the subject." The reviewer particularly welcomes the absence of erroneous theories and the results of faulty work of earlier investigators, which sort of material is often included by authors in a historical treatment of the subject. The book is remarkably free from typographical errors. Those whose interests lie in industrial fields might desire a fuller discussion of the rôle of mercury salts in the conversion of acetylene to acetaldehyde and also the mercury compounds of ethylene, since the latter also promise to be of industrial interest. Also the very fact that the biological and pharmacological literature is in such unsatisfactory condition, as noted by Dr. Whitmore, suggests that the same critical treatment of this phase of the subject by him would add greatly to the value of the book, at least for a certain class of readers. Nevertheless, the care which Prof. Whitmore has obviously given the preparation of this volume is a service which should be appreciated by all organic chemists. It has seldom been the privilege of the reviewer to read a monograph on any subject of chemistry which he could commend so unservedly.

BENJAMIN T. BROOKS.

WASTE IN INDUSTRY. By the *Committee on Elimination of Waste in Industry* of the Federated American Engineering Societies. Published by Federated American Engineering Societies, Washington, D. C., and sold by the McGraw-Hill Book Co., Inc., New York. 410 pages, illustrated. Price \$4.

This is a report of the Committee on Elimination of Waste in Industry of the Federated American Engineering Societies, appointed by Herbert Hoover, the first president of that organization. It represents an intensive study of six typical branches of American industry undertaken for the purpose of gathering quickly data and information that would permit of a comparison of average practice with the best-known practice. Such a study, it was expected, would disclose the nature, cause and extent of preventable waste. The analysis was based on a questionnaire which had been devised for obtaining such quantitative data as the industries possessed. The work was completed in 5 months. On studying the report one is impressed with the fact that American industry is marked by preventable waste of great magnitude which if properly brought to the attention of those responsible for the financial support and commercial success of our industries would stimulate them to keener introspection and consequent improvement of their processes of production and distribution. From this point of view the report merits the careful study of financiers, business leaders, labor leaders, industrial engineers, economists and others in positions of authority and responsibility.

The sources and causes of waste in industry are attributed by the committee to: 1, low production; 2, interrupted production; 3, restricted production; 4, lost production. In seeking to place responsibility for these wastes the committee came to the conclusion that "over 50 per cent of the responsibility for these wastes can be placed at the door of the management and less than 25 per cent at the door of labor, while the amount chargeable to outside contacts is least of all. It must be recognized that if management is to meet this responsibility fully it must have the co-operation of labor."

Low production is to be ascribed mainly to faulty control of material, design and production; lack of knowledge of costs and lack of cost control; lack of research; faulty labor and sales policies. Interrupted production is a consequence of idle men whose unemployment is due to seasonal occupation, industrial depression or labor disturbances. The committee dispels a popular notion that the waste due to unemployment on account of labor disturbances is high. As a matter of fact, the amount of waste from strikes and lockouts in general is much less than is popularly supposed. Seasonal unemployment, however, is a factor of great importance in such industries as building, shoemaking and bituminous coal mining. In 1919, a year of exceptionally regular employment, the percentage of full time worked in the brick, chemical and glass industries was 85, 84 and 87 respectively. The margin of unemployment in all industry in our best years has never been less than one million men.

In restricted production due to rules and regulations of labor unions the committee finds a serious cause of waste. To the average reader many of these restrictions will appear inconceivable, affronting the intelligence of reasonable men. Lost production due to ill health and accidents is found to run into figures that are beyond comprehension, but which, nevertheless, measure the great waste arising from disease and accidents.

A chapter is devoted to the committee's recommendations for eliminating waste. Having placed a large share of the responsibility upon management, it outlines a way in which this responsibility can be met. It is largely through improvement in organization and executive control, applying sound and modern principles to production, costs, sales, purchase and personnel. Simplification and standardization of processes, equipment and products will do much to eliminate waste. Labor is held responsible for co-operation in increasing production by changing its rules that restrict output unreasonably. It is also held accountable for co-operation in the plans of management for standardization and improvement of industrial relations. The public is called upon to contribute to waste elimination by being less exacting in its demand for changes in style. The public can also assist in stabilizing industry by distributing demand in certain seasonal industries throughout the year, as in the building industry.

The committee sees an opportunity for governmental assistance through the establishment and maintenance of a national industrial information service and a national statistical service. These are functions which the Secretary of Commerce is now trying to exercise in co-operation with various industries by issuing monthly figures on production, consumption and stocks.

The industries that were investigated and on which detailed reports are made in Chapter V are building, men's clothing, shoemaking, printing, textile manufacturing and metal trades. The separate reports in these industries are accompanied by a questionnaire and the field report evaluation. While they are of particular value to the industries studied, they are suggestive to all industries and to all establishments, large or small. It is inconceivable that any manager, for example, can spend a period of serious reflection on the questionnaire, with respect to his own establishment, without having his attention directed to wasteful practices that can be changed. Indeed, this is the principal value to be gained from the widespread reading of the book.

Part III is concerned with some reports on unemployment, strikes and lockouts, legal machinery for adjusting disputes, industrial accidents, health of industrial workers, eye conservation, purchasing and sales policies. These are general summaries of available information compiled by competent critics. They have a supplementary value by emphasizing some of the causes of waste disclosed by the committee and by focusing attention on further means for solving the problem. On the whole the book represents a useful study that will be productive of further investigations and of a more critical attitude toward waste on the part of all who read it.

H. C. PARMELEE.

Senate Sub-Committee Appointed to Investigate Dye Industry and Practices of Dye Importers

The Senate's investigation of the legislative activities of the domestic dye industry and of the practices of dye importers will be conducted by a sub-committee of the Judiciary Committee to be composed of Senator Shortridge of California, Senator Borah of Idaho and Senator Reed of Missouri. No date has been set for the hearings.

Dates Set for Rate Reduction Arguments Before Interstate Commerce Commission

Representatives of the fertilizer, sulphuric acid and phosphate rock industries will make their arguments in the rate reduction case now before the Interstate Commerce Commission on Jan. 28. Representatives of the vegetable oil and soap industries will appear on Feb. 8.

"Open Competition" Plan of Hardwood Manufacturers Association Declared Illegal

In a decision made public Dec. 19 the United States Supreme Court declared the "open competition" plan of the American Hardwood Manufacturers Association a restraint upon trade in violation of the Sherman anti-trust law. The association, consisting of 603 individuals and corporations, was charged, in the suit brought by the government, with enhancement of prices through exchange of bulletins and reports on stocks, prices and production.

Gas Leaves No Permanent Injury, Survey by C. W. S. Shows

The Chemical Warfare Service has completed its survey of chemical plants and finds that the manufacturers of chlorine, heavy chemicals and other materials that produce gases similar to those used in war have no record of any permanent disability which followed the gassing of an employee.

In the research, proving development and care of the various chemicals and war gases at Edgewood Arsenal there has not been a fatal accident or permanent injury from gas since the armistice, but no week passes without one or more men being gassed to the extent of causing temporary inconvenience.

Anti-Chemical Propaganda Rife—Measures Suggested to Combat It

A country-wide propaganda apparently is on foot, which, while striking mainly at chemical warfare, shows signs of being hostile to American chemical development in general. Some profess to see behind this movement the encouragement of German dye interests, but regardless of the real source of the movement, there is evidence to show that it is being carried on in a systematic and active manner. Very material assistance is being given this effort by persons of good standing who have not taken the trouble to inquire into both sides of the chemical question. To meet this organized effort, leaders among chemists are of the opinion that it can be offset best if individual chemists throughout the country will make an effort to disseminate in their own locality the truth as to chemical warfare and to the current situation which confronts the chemical industry. There is a feeling that the domestic chemical industry has confined its attention too largely to the erection of a superstructure in Washington for which there is an insufficient base, formed by public opinion.

The whole anti-chemical movement has received great impetus from the action of the advisory committee to the

American delegation at the Conference on Limitation of Armament. This report has not been made public, but it is no longer a secret that the advisory committee has recommended that chemical warfare be prohibited by international agreement. A reaction has set up in the advisory committee itself in regard to that report, it is understood. Some members of the committee now are said to feel that this report was forwarded to the commission without due consideration and it is altogether probable that it will be recalled for modification, at least.

Claims are being made widely that public opinion in the United States demands the abolition of chemical warfare. It is admitted by the friends of chemical warfare that the public has been apathetic in its attitude, but they claim that among those who have gone into the merits of the subject only an insignificant proportion believes that chemical warfare can be abolished by agreement any more than war itself can be abolished by agreement. Writers of editorials in newspapers throughout the country seem to be well advised on the subject and the overwhelming percentage not only expresses the opinion that gas has come to stay as a military weapon, but is inclined to the belief that it may be more humane than the weapons now more largely used. In that connection it may be mentioned that the controversy about gas was threshed over extensively before committees of Congress and that a deliberate conclusion in favor of gas was reached.

National Research Council's Information Service to Advise "Where to Buy"

As a part of the service to investigators generally, the Research Information Service of the National Research Council is preparing itself to supply information regarding research instruments, apparatus and supplies. This service is apparently a much needed one, for the Council is frequently receiving requests now as to where special types of apparatus or special research facilities may be procured.

It will be the effort of the information service to have available sufficient information from all sources of such equipment and supplies that it may promptly advise investigators where things needed may be quickly obtained. Some of the recent queries asked where the inquirer may purchase such things as a human skull, a selenium cell, lantern slides on European geography, a Lummer-Brodhun photometric cube, inexpensive photomicrographic apparatus, recording gages which indicate fractions of an ounce, apparatus for the study of the sensitiveness of photographic plates, and a multitude of other "specials."

In general the queries represent needs of investigators who cannot well have on hand complete files of catalogs because it is only occasionally that such special facilities are required in most small laboratories. It is hoped by the Council, therefore, that research workers generally when in doubt can be materially assisted through the complete files which it will be worth while for the Council to maintain as a part of this service. Anyone desiring information and those wishing to make sure that the facilities which they offer for sale are on record in the Council office should address Research Information Service, National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Mexico to Increase Tariff Rates

On January 1 a new tariff schedule will be effective in Mexico which will increase rates on various commodities from 50 to 100 per cent. Candy, leather goods, woollens, furniture, silk, brooms and chemical products are to be taxed 50 per cent more than the present rate, while matches, soap, tobacco and toilet waters have been placed in the 100 per cent list.

PHOTO TAKEN ON STEPS ON WINANTS HALL, RUTGERS COLLEGE

Annual Meeting of the New Jersey Clay Workers' Association

The annual meeting of the New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society, held at New Brunswick, N. J., Friday, Dec. 16, surpassed in many ways any previous gathering of the organization. The papers were timely, practical and decidedly instructive; the discussions equally illuminating; and the attendance excellent.

Morning and afternoon sessions took place in the Fine Arts Room, Queen's Building, Rutgers College, and the hall was well filled when the meeting was called to order shortly after 10 o'clock, with President Abel Hansen, head of the Fords Porcelain Works, presiding.

CERAMIC SCHOOL WELL UNDER WAY

In his opening address President Hansen made particular reference to the new ceramic school and research station now in course of erection and which is expected to be ready for occupancy in the spring of next year. He said that the completion would mark a new milestone in the history of the ceramic industry of the state, and he urged that every support, financial and moral, be given to the enterprise.

He spoke also of the need for defined quality products in the ceramic field, and said that systematic education was necessary to bring about a full appreciation of American wares as compared with the general run of foreign production.

BRIEF BUSINESS SESSION

Secretary George H. Brown, director, department of ceramics, Rutgers College, presented an interesting report, covering the minutes of the last annual gathering as well as numerous details and features pertaining to the new school building. He mentioned the generous contributions received toward the erection of the structure from different companies in the ceramic industry, and the enterprising work of different committees appointed in this direction.

R. H. Minton, General Ceramics Co., chairman of the committee appointed to draft new bylaws for the association conforming to those of the American Ceramic Society, presented the set of rules as arranged by the committee. These were adopted by a unanimous vote, without change.

COMPOSITION OF PORCELAIN BODIES

The first paper of the technical session was "Notes on the Effect of Composition on the Mechanical Strength of Porcelain Bodies," by Prof. Brown and C. C. Clarke, department of ceramics, Rutgers College.

The treatise set forth the results of a comprehensive series of tests of ten different porcelain bodies to determine the transverse strength of the material. The bodies were fired in regular commercial kilns, maturing at cones 7 and 8. The body compositions were varied with fundamental view of securing definite data as to the effect of the relative contents of flint and feldspar on the mechanical strength of the bodies.

The results of this work go to confirm the theory that a

high flint content is conducive to greater mechanical strength. In this, however, it was pointed out that a high flint content cannot be held as being desirable for all types of porcelain bodies, and primarily, those which are subjected to wide temperature changes in use. In the latter body the gain in mechanical strength is likely to be more than offset by the tendency of the high and irregular coefficient of expansion of the flint, bringing about fracture in heating and cooling.

The high strength developed by the high feldspar body, stated at 55 per cent, has points of merit to warrant more extended investigations, and particularly so in the case of low-fire compositions, such as are used in the production of tableware and kindred specialties, and the high feldspar bodies so popular in the manufacture of vitreous floor tile.

In the high flint end of the different bodies and tests, there did not appear to be a direct relation between porosity and mechanical strength. Accordingly, it would seem that a porcelain body does not necessarily attain its maximum strength when it has developed minimum porosity.

The results of the tests were shown by illustrated references in the form of charts, flashed on the screen, the curves being plotted in a manner for ready comprehension.

MANUFACTURE OF ELECTRICAL PORCELAIN

The next paper was an interesting résumé of electrical porcelain manufacture by T. A. Klinefelter, Atlantic Terra Cotta Co., Tottenville, Staten Island, under the head of "Some Notes on Materials and Processes in Electrical Porcelain Manufacture."

Speaking from notes, Mr. Klinefelter showed his knowledge and intimacy of the subject by taking up each phase of production, from the raw clay to finished article. Considering briefly electrical porcelain for low-tension work, such as sockets, cutouts, fuse blocks, etc., he explained the common methods of quantity production and showed how attractive this field has become to different manufacturers.

Electrical porcelain for high-tension service, he set forth, was an entirely different proposition, requiring great care and attention in manufacture. For voltages up to 70,000 and 75,000 and above he said that $\frac{1}{4}$ -in. material was the usual practice, while for 110,000 v. and even higher, $\frac{3}{4}$ -in. porcelain was being used. For service ranging around 40,000 v., $\frac{1}{2}$ -in. material is the customary thickness.

The material for first-grade electrical porcelain must have such characteristics as great strength, great density, great resistance to impact and resistance to severe temperature changes. Firing is carried out to cones 11 and 12 for such class of material, while for low-voltage service, burning to cones 8 and 9 answers all requirements. The usual clay mixtures for high-tension porcelain average from 40 to 60 per cent of clay, 20 to 25 per cent of feldspar and from 20 to 15 per cent of flint.

Reference was made to the different types of equipment in use. In the plant in question, regular updraft, round kilns are employed, and the speaker pointed out the indicated possibilities of tunnel kilns and compartment kilns for this work. With regard to pug mills, he said that there was great room for improvement, while diaphragm

pumps were recommended strongly for work in connection with the handling of the slip. The modern humidity drier was referred to as a great achievement, permitting the drying of ware in from 60 to 70 hours as compared with from 2 to 3 months in time gone by.

The tests made upon insulators for high line service were explained in an interesting way. In this the high frequency test is carried to voltages considerably in excess of those in standard commercial practice, sometimes running to three times above without "splashing" in attaining the "flash over" point.

An important reference made by Mr. Klinefelter covered a plea for the development of standard specifications for the purchase of clays, flint, feldspar and other raw materials, eliminating the "guess" method now prevailing. Such specifications, he said, arranged in a logical and fair-minded way, would help the purchaser, dealer and clay miner, and other parties concerned.

NICKEL SALT EFFECT UPON COLOR

The concluding paper of the morning session was "The Effect of Nickel Salt on the Color," by G. M. Tucker, New York Architectural Terra Cotta Co., Long Island City.

This was a brief digest of plant experience and experiment, illustrating the uncertain quality of color reproduction in using nickel salt for terra cotta glazes. It was pointed out that it was practically impossible to utilize nickel in certain glazes for a definite color. A number of interesting specimens of work were shown.

ELECTION OF OFFICERS

Just prior to adjournment for luncheon an election of officers was held, and the following recommendations of the nominating committee were approved for the ensuing year:

President, R. H. Minton, General Ceramics Co., Metuchen, N. J.; vice-president, Andrew Foltz, Lambertville Pottery Co., Lambertville, N. J.; councilor, Charles A. Bloomfield, Bloomfield Clay Co., Metuchen, N. J. (re-elected); and secretary and treasurer, George H. Brown, department of ceramics, Rutgers College.

The executive committee will be composed of eighteen members, in addition to the officers noted, including Abel Hansen, chairman, ex-president; August Staudt, Perth Amboy Tile Works, ex-president; and Charles Howell Cook, Cook Pottery Co., ex-president. The terms of five of the remaining fifteen members will expire in 1922; five others in 1923; and the remaining five in 1924.

PROPERTIES OF SOME BALL CLAYS

Following an hour given over to luncheon, the afternoon session was called to order by President-elect Minton close to 2:30. He made a few appropriate remarks, asking for the support of all members during his term of office. He made a plea also for increased membership during the coming year, and prior to the adjournment for the day about twenty names were added to the roster.

The afternoon technical session was opened by H. H. Sortwell, Bureau of Standards, Washington, D. C., with an interesting paper dealing with "The Properties of Some Ball Clays," illustrated with lantern slides showing different test tables.

The speaker explained the investigations now being made by the bureau of different ball clays, both of English and American origin. The properties of Kentucky clays, Tennessee clays, Dorset and other clays were enumerated, with explanation of their behavior under different tests, and the indicated desirability for certain character of manufacture.

FIREBRICK MANUFACTURE

Following this, F. B. Allen, of the M. D. Valentine & Bro. Co., Woodbridge, N. J., read an illuminating paper entitled, "The Manufacture of Soft-Mud Firebrick," describing the different phases of manufacture at the Valentine plant. This factory has been operating since 1865, and has grown from one kiln to nine kilns, with rated production of approximately 600,000 firebricks per month.

Extended reference was made to recent plant improvements for increased efficiency, including the installation of

considerable new machinery, such as clay granulator, disintegrator, soft-mud brick machine, mechanical driers, gravity conveyors, etc.

A DISCUSSION ON KILNS

The illness of the last speaker on the program, T. A. Shegog, ceramic chemist for the Ellis-Foster Co., Montclair, N. J., prevented the presentation of the final paper on the subject of "Principles and Practice of Kiln Firing." Accordingly President Minton gave the meeting over to a general discussion of kilns, and a valuable hour's talk ensued.

Consideration was given to tunnel kilns and compartment kilns primarily, with interesting points brought out by Mr. Minton in opening the discussion, August Staudt, T. A. Klinefelter, Leslie Brown (Lenox, Inc.), C. W. Hill (Atlantic Terra Cotta Co.), and others.

Co-operation Between Universities and Industries Discussed Before Chicago Section, A.C.S.

Dr. John Johnston, chairman of the department of chemistry, Yale University, spoke before the Chicago Section of the American Chemical Society, Dec. 16, on the question of co-operation between universities and industries. His address is outlined in the following paragraphs.

The problem of the universities is to produce men whom the industry wants, and men who will carry into industry the best spirit of advancement. It is a problem of training them to do their part in the world's work, and of developing them to the maximum of their abilities to so carry on. These men must be capable of developing new knowledge and of applying present knowledge to industry.

Teaching of chemistry in the universities does not separate these two phases. It is attempted to give some degree of industrial application of the subject as well as developing the research phase. The student cannot easily grasp a situation without some knowledge of industrial application. Industry needs a continuous supply of well-trained men, and the university is the only source of supply. Of course, industry may train men who have already had previous training, but not in proportion to its needs. Therefore, industry is the consumer.

The university must have the co-operation of industry through financial assistance and fellowships, going just as far as is compatible with the real function of the university. Each proposal to help must be judged as to whether it contributes to the training of men. It is not always possible to tell at a glance about any one proposal, but if there is any merit to it at all, it must be tried out to see if it constitutes a problem. If it is routine, it should not be done by the university.

Industry should use the university teacher as a consultant, if he is qualified by experience and doesn't take too much of his time at this work. It is advisable because it gives him connection and contact with industry and he learns to get along with people. The average college professor is too individualistic. He can never make a decision without reservations. His work as a consultant should be on a rather small scale, and he must have permission to publish his results. Research is often misnamed in industry, and the term is applied to something which is simply an artifice. This sort of research should be carried on by the industry. There is no difference between fundamental research and pure research, for industry. We are sadly lacking in fundamental knowledge as to alloys and the corrosion of metals, for instance. There is no theory now published that is worth a row of pins. The study of the mechanism of catalysis is more important than the discovery of an individual catalytic process.

One of the problems is to induce more students to stay and get a thorough training at the university. It cannot be done by giving them routine analysis as pot boilers. Where consulting work is done, consultant fees should be charged and the student should get a small part of the fee only, the rest going to the maintenance of the university department. That the professor should get part of his salary by outside work is only a partial solution of the financial situation. It does help to keep some in the teach-

ing business, and they should be allowed to consult within reason.

Fundamental research costs a great deal of money, and therefore the universities cannot finance much industrial research. Research is a form of insurance against ignorance. Industry has developed a bad opinion of the research men because many have been recommended for positions who are inadequately trained. One \$10,000 a year man is worth many \$2,000 a year men. So the university must discover and train \$10,000 men. The university can co-operate by training this high type of man which industry needs. Since the subject of chemistry is nearly twice as large as formerly, a man cannot be adequately trained in less than 6 or 7 years at the university.

It is a well-known fact that the technical man is not considered as the highest type of professional man, both socially and otherwise. The best men who come to the universities never think of the technical professions for this reason, but they rather turn to law and medicine. This is mainly because more money is involved; but no more brains are required in law and medicine than in chemistry. The doctor and lawyer are held in much higher social esteem than the chemist.

The technical efficiency of industry is not over 50 per cent, and in many industries not over 10 per cent. Germany gets by well because the heads of concerns are technically trained men. This is true in the United States in the electrical industry only.

It is to be hoped that industry will contribute to fellowships which the universities cannot afford, and will permit them to go on a completely unrestricted basis. The publication of results within a short time is an important essential. Great benefit would be derived by an interchange of men between the industries and the universities. No university should have vocational courses.

DISCUSSION

Dr. Johnston's paper was followed by a warm discussion by both industrial and university members of the section. Dr. Evans, of Northwestern University, suggested that more students might be held in chemistry by giving them a lighter course the first year, and selling them the idea of the great benefit of chemistry in industry. Dr. David Klein, of Wilson & Co., packers, said that if industry was only on a 10 per cent basis, technically, then the universities were operating on less than a 5 per cent basis as educational institutions. He further suggested that the universities might well train their students to some knowledge of the ordinary business conditions which they would meet on leaving the university.

Production Costs in the Lithopone Industry, January-July, 1921

A study of the costs of producing lithopone during the first 6 months of 1921 shows a considerable increase over the costs during the same period of 1919. The results of this investigation, which was made by the Tariff Commission at a request of a committee representing the domestic manufacturers, have recently been published in a report by C. R. DeLong of the chemical division and E. M. Whitcomb of the accounting division of the commission's staff. The report points out that although the manufacturers reported their costs on a more uniform basis than in the previous investigation,¹ there was still a noticeable lack of uniformity in the methods of treating certain cost items. The outstanding differences are principally in the

methods of handling raw material charges, determining sales expenses and in the treatment of administrative expenses.

The weighted average cost of lithopone for all companies during the first 6 months of 1921 are compared with the same 6 months' periods in 1919 in the accompanying table. This table shows also the distribution of total cost to the items—material, direct labor, factory overhead and selling expense. Column 9 shows the average profit for the industry by deducting the total cost from the average net sales price, as shown in column 8.

The increase in total cost is accounted for largely by the increase in factory overhead expense per pound of lithopone, which more than offset the decrease of 0.26 of a cent per pound in direct labor and a slight decrease in selling expense. The total cost of producing lithopone was distributed as follows: 42 per cent for raw materials, 13 per cent for direct labor, 41 per cent for factory overhead, and about 4 per cent for sales expense.

The total quantity of lithopone produced is only about one-half the output during the last half of 1919, when the industry was operating at a maximum capacity. Without doubt this restricted production is mainly responsible for the increase in total unit cost.

Only eight of the thirteen firms previously engaged in lithopone production were in actual operation during this period. Considering existing plants, the industry was in operation only to the extent of one-third of its capacity, and the eight firms which were operating manufactured lithopone equal to only about 40 per cent of their capacity. It is pointed out, however, that this inactivity is not due to competition from imported lithopone, as imports equaled only 2 per cent of domestic sales.

German Labor Situation

From reliable sources in Germany the Department of Commerce is advised that labor unrest is again appearing in that country, concurrently with the sharp decline in the value of the German mark and advancing costs of necessary food and clothing there. Workers in the engineering and steel industries of the Düsseldorf area are now striking for increases in wage rates. It is said to be difficult to maintain operations in the most essential continuous processes of the plants at Düsseldorf. As a general average the striking workers are demanding a 75 per cent increase in wages.

In the Krupp works at Essen, employing about 50,000 men, a formal demand has just been presented to the management for a "living cost bonus" of 2,000 marks per month to each employee. A bonus is required by these workers because of the recent and continuous price advances of necessities in terms of their currency.

It is not expected that this demand of labor will remain disputed long, for it seems clearly recognized, both within and outside Germany, that the profits of manufacturers from exports are enormous, particularly while the mark is on the decline and as long as domestic costs of production lag behind the depreciation of currency.

Costs, other than labor, are already increasing, however, in marks. Railroad freights, which were advanced 30 per cent on Nov. 15, were subjected again to another 50 per cent increase on Dec. 1, thus giving a combined advance of approximately 95 per cent in a fortnight. The price of coal is shortly to be made 150 marks more per ton.

The prices of pig iron and tin plate, as of other steel products, have just been extended greatly to cover depreciation of the mark and growing costs of production. And yet foreign orders are said to be numerous, and the plant managers decline to give delivery promises under 4 months.

WEIGHTED AVERAGE COST OF LITHOPONE FOR 1919 AND FIRST 6 MONTHS 1921

1	2	3	4	5	6	7	8	9
Period	Production (Pounds)	Total Cost	Material Cost	Direct Labor Cost	Overhead Factory	Selling Expense	Average Net Sales Price	Apparent Average Profit
1921 (First six months)	45,150,036	\$0.0626	\$0.0263	\$0.0082	\$0.0258	\$0.0023	\$0.0676	\$0.0050
1919 (First 6 months).....	53,092,739	0.0605	0.0258	0.0102	0.0215	0.0030	0.0671*	0.0066
1919 (Last 6 months).....	89,426,437	0.0600	0.0259	0.0111	0.0199	0.0031	0.0653*	0.0053

Professor Moureu Lectures on Rare Gases at Columbia University

Dr. Charles Moureu, professor of chemistry at the Collège de France, who is now in this country as technical adviser to the French Mission for Disarmament, delivered a very instructive address on "Natural Gases, With Special Reference to the Rare Gases," in Havemeyer Hall, Columbia University, Dec. 20.

After reviewing briefly the history of the discovery of the five rare gases—argon, neon, helium, krypton and xenon—he outlined the results of his studies on these gases as found in the atmosphere, thermal springs, firedamp and natural gases. A special apparatus for the separation and purification of the gases was illustrated and described.

A thorough study of hundreds of French thermal springs has shown an almost universal occurrence of these gases, although the quantity varies greatly with the locality, some springs having only infinitesimal amounts, while the gases from the Source Carnot of Santenay contain over 10 per cent of rare gases, helium predominating. The springs are radioactive as a rule, but the amount of radium emanation present is not proportional to the quantity of rare gases.

From numerous studies it has been shown that the proportion of rare gases in the atmosphere is fairly constant. If the ratio of the quantities of any two of the rare gases in the atmosphere is compared with the ratio for the same gases from the thermal springs, a remarkable similarity is noted. Thus if the ratio krypton:argon in air is taken as 1, the ratio krypton:argon in the gases from thermal springs does not vary much from 1. This constancy is not noted in ratios involving helium, however, because of the fact that helium is being produced by the decomposition of radium in the vicinity of radioactive springs. The ratios involving neon are being studied at the present time. Since the main constituent of the gases from thermal springs is what Prof. Moureu calls "crude nitrogen"—that is, nitrogen plus the rare gases—ratios with nitrogen were also studied and the results were fairly constant considering the relatively greater chemical activity of nitrogen. From all these observations Prof. Moureu concludes that the inert gases occur today in the same relative proportions as when the earth was formed from nebulous material.

Similar studies have been made of firedamp in the various French coal mines and of other natural gases. Prof. Moureu also touched briefly upon the work done with American natural gas and the great practical importance of these studies.

In the evening Prof. Moureu was the guest of honor at a dinner at the Chemists' Club given by the American Section of the Société de Chimie Industrielle.

"Ghosts" and Elongated Structure of Drawn Wires Discussed at Washington Chapter, A.S.S.T.

The elongated structure produced by heavy drafts in wire drawing may be readily removed by suitable annealing, whereas in the case of "ghosts" only a partial removal of this structure is effected and there remain the elongated non-metallic inclusions high in phosphorus and sulphur which pass through the grains producing lines of weakness. At a meeting of the Washington Chapter, American Society for Steel Treating, Dec. 16, the occurrences and differences between these "ghost lines" and the elongated structure produced in wire drawing were discussed by N. B. Hoffman, metallurgist of the Colonial Steel Co., Pittsburgh.

The magnitudes of the effects of "ghost lines" in low-carbon steel wire vary in individual cases, but for the numerous examples presented the tensile properties were reduced by about 26 per cent. Stead's copper reagent may be used to show the outline of the "ghosts" due to the fact that the areas low in phosphorus are first covered with copper. If the samples are washed the "ghost lines" high in phosphorus, to which the copper has not adhered, will then clearly be shown.

The January meeting of the section will be addressed by T. Holland Nelson, steel-works manager of H. Disston & Sons, Philadelphia, who will speak on "A Comparison of American and English Methods of Producing High-Grade Crucible Steel."

Number of Plants Increasing Operations Still Growing

Paper. The International Paper Co., 30 Broad St., New York, has increased production at its different mills about 100 tons daily since the first of the month, bringing the output up to about 1,000 tons per day for all varieties of paper. The company is planning for a gradual increase in manufacture to a maximum of 1,800 tons daily.

The York Haven Paper Co., York Haven, Pa., is maintaining active production at its mills, and is distributing a Christmas bonus to its 300 employees totaling about \$10,000. The fund represents 5 per cent of the employees' earnings during the past 6 months.

Glass. The Scott-Warman Glass Co., East Stroudsburg, Pa., has resumed production at its plant after a considerable period of curtailment. Orders received are said to insure continuous operations for some time to come.

Rubber. The B. F. Goodrich Co., Akron, Ohio, has increased production to a point of 16,000 tires a day, or about twice the number manufactured in recent months. It is planned to advance the output gradually until a maximum of 20,000 tires daily is reached.

The Kelly-Springfield Tire Co., Cumberland, Md., has started a night shift at its local plant.

The Goodyear Tire & Rubber Co., Akron, Ohio, is operating its local plant on a basis of 16,000 tires per day.

Copper. The Raritan Copper Works of the Anaconda Copper Co., Perth Amboy, N. J., has opened a number of departments at the local plant, giving employment to an increased number of operatives.

Iron and Steel. The Logan Iron & Steel Co., Lewistown, Pa., has recently resumed operations at its puddle mills, giving employment to an increased working force.

The Bethlehem Steel Co., Bethlehem, Pa., is resuming operations in a number of departments at its Steelton, Pa., works, following an extended period of curtailment.

The Wheeling Steel Corporation has resumed full operations at its Benwood (W. Va.) tube works, giving employment to a full quota of 1,500 men. The company is also operating its top mill furnaces at 100 per cent capacity.

The Gulf States Steel Co., Gadsden, Ala., is operating at record capacity at its local plant, with full working force. New high production totals are being established.

The United Alloy Steel Corporation, Canton, Ohio, is operating on a basis of more than 50 per cent of normal, and is said to be planning for an early increase.

The American Steel Foundries, East St. Louis, Ill., is increasing production at its different plants and will be running soon at over 60 per cent of normal, as compared with 25 to 30 per cent capacity in September and October. Operations recently were resumed at the Alliance, Ohio, works, following a shutdown for several months.

The United States Steel Corporation, New York, has increased production at its various mills to about 50 per cent of normal.

Tin Plate. The McKeesport Tin Plate Co., McKeesport, Pa., is operating its forty-four mills on full time, giving employment to about 3,000 men.

The American Sheet & Tin Plate Co. has resumed full operations at its Farrell Works, Sharon, Pa., effective Dec. 18, placing six hot mills in service, making a total of thirty mills in active production at the plant.

Work of Chemical Division, Bureau of Internal Revenue

A total of 39,474 samples were analyzed by the chemical division of the Bureau of Internal Revenue during the last fiscal year, the annual report of the Commissioner which was submitted to Congress Dec. 5 shows. These samples comprised butter, oleomargarine, fats, oils, narcotic drugs, fermented beverages, distilled spirits, denatured alcohol and medicinal preparations. The laboratory work of the bureau has been greatly increased by the laws governing the administration of preparations containing alcohol. The extension of the use of alcohol free of tax has also added materially to the work of the industrial alcohol section, the report shows. The number of bonded manufacturers using specially denatured alcohol increased from 1,395 during the previous year to 1,761.

War Department Sells Sodium Nitrate

The War Department has disposed of 81,000 long tons of its reserve of sodium nitrate. The awards were made to the highest bidders for the various lots of the material located at a number of warehouses throughout the country. The prices ranged from \$34.94 to \$46.50 per ton. The purchasers of the larger amounts were: Hercules Powder Co., Wilmington, Del., 20,017 tons; E. I. du Pont de Nemours & Co., Wilmington, 18,600 tons; Wessel-Duval Co., New York, 18,000 tons; G. S. Alexander & Co., New York, 10,167 tons; Merrimac Chemical Co., Boston, 4,408 tons. Other purchasers were: Armour Fertilizer Works, Chicago; Equitable Powder Co., East Alton, Ill.; Senior Powder Co., Cincinnati; Southern Acid & Sulphur Co., St. Louis.

Chicago Chemists Club Night

The first evening social event of the Chicago Chemists Club's winter season occurred Saturday, Dec. 17. After dinner, served in the main dining room, the members and the ladies danced until a late hour. Novel entertainment features between the dances gave a well-rounded program.

Obituary

ROBERT H. MCKEAN, manager of the credit department of the McGraw-Hill Co., Inc., died at his home on Dec. 17, 1921, at 2 a.m. Mr. McKean's services began with *Engineering and Mining Journal* in April, 1902, as assistant in the accounting department. Within 2 years he had been promoted to the position of head bookkeeper and at the time the *Journal* was purchased by Mr. Hill he was in charge of the accounting department. About a year after the purchase of *Engineering and Mining Journal* by the Hill Publishing Co. Mr. McKean was appointed manager of the *Journal*, which position he held until he was elected a director and secretary of the Hill Publishing Co. At this time he assumed the management of the credit department of the company. He was a director and secretary of the Hill Publishing Co. until its consolidation with the McGraw Publishing Co. After the consolidation he became manager of the combined credit departments and held this position until his death. Mr. McKean's loss to the McGraw-Hill Co., Inc., will be a serious one, because of his unusual ability in his chosen work. His ready wit and keen sense of humor will be missed by his associates.

REUBEN L. LINDSTROM, superintendent Point St. Charles plant, Canadian Steel Foundries, Ltd., died on Dec. 12 at his home in Montreal. He left the Bettendorf Company, Bettendorf, Iowa, four years ago to become metallurgist with the Canadian Steel Foundries, Ltd., which position he filled until appointed superintendent of the Point St. Charles works 18 months ago.

Personal

Dr. CHARLES BASKERVILLE, professor of chemistry of the College of the City of New York, gave an address on Science and Civilization: The Rôle of Chemistry," before the members of the Pittsburgh Section of the American Chemical Society on Dec. 13.

LEWIS H. CARLSON has severed his connection with the Frederick Stearns Co. and has organized the Chemicals Sales Co., of which he is president.

HOLLIS H. DANN, recently chief chemist at Central Fe, Cuba, has become associated with the Darco Corporation, of Wilmington, Del., as technical assistant to the sales manager. Mr. Dann will have charge of the development work in connection with the cane sugar industry.

FRED C. HAHN, research chemist at the Marcus Hook plant of the National Aniline and Chemical Co., has been given a leave of absence to complete graduate work at Johns Hopkins University.

P. H. HART has been elected treasurer of the Goodyear Tire & Rubber Co., Akron, Ohio, succeeding H. H. Springfield, who has become assistant to the president.

HUGH M. HENTON has resigned the instructorship in metallurgy at Case School of Applied Science, and has opened an office in the National City Building, Cleveland, Ohio, as consulting engineer in metallurgy and mining.

ARTHUR H. HUISKEN, formerly of the Baltimore Copper Works, is now with the Research Laboratory of the Edgewood Arsenal, Edgewood, Md.

ALBERT E. MARSHALL, formerly chemical engineer for the Davison Chemical Co., has severed his connection with that organization and has opened an office in Baltimore for consulting work.

Dr. H. H. MORRIS has recently resigned from the chemical department of E. I. du Pont de Nemours & Co. to take charge of the research department of the Bond Manufacturing Corporation, Wilmington, Del.

ALBERT W. SMITH, formerly dean of Sibley College, Cornell University, is now a consulting engineer with the firm of Henry R. Kent & Co., New York and Boston. Dean Smith's work will lie particularly in consultation on thermodynamic and mechanical engineering for chemical plants.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Dec. 24, 1921.

The chemical market during the past week showed no signs of any radical changes and transactions in most cases were limited to small quantities. The movement was somewhat irregular and fully in line with pre-holiday seasons. A great deal of optimism, however, is expressed by leading factors, who stated that outside influences are making for betterment in trade conditions, and with this in mind there are few indeed that do not expect an expansion in business during the early part of next year.

The export situation has also been an encouraging feature to traders and frequent inquiries are still reaching the market from various sections of Europe, the Orient and South American countries. Although actual transactions among exporters were limited, owing to the differential in quotations on spot and the prices given to exporters from their foreign customers, the fact that inquiries were freer is an encouraging sign for future prosperity. The advance in foreign exchange rates is favorable to our industry in many respects. The biggest thing that could be brought about through this advance is the opening up of export channels to permit the absorption of our surplus chemical stocks. There is also no doubt that foreign products imported to this country would bring higher prices with a stronger money market. Importations still continue with unceasing rapidity at relatively low prices and have kept the consumer from paying a price on domestic material. Adjustments are constantly taking place and it is certain that 1922 will find domestic manufacturers ready to compete in a more favorable manner than at any time since the war.

The rise of yellow prussiate of soda still continued to be the feature of the week's activities. This commodity is practically the only one to fall in line with the rise in sterling. Spot stocks seem to be well sold up and domestic producers have been turning away round lot business. Orders on hand are reported to keep factors busy far into January. On the other hand, there is an easier tone prevailing in the market on caustic soda, soda ash and caustic potash. These chemicals have become quite dormant in the past two weeks and a keener state of competition has developed. Glycerine and tin oxide have been advanced by leading makers during the week and trading in general seems to have been very satisfactory on these items. Imported chlorate of potash has also shown a little better tone, although prices are considerably lower than those quoted by domestic manufacturers. Oxalic acid is moderately active, especially in small-quantity orders to regular

consuming channels. Cream of tartar prices eased up somewhat and domestic producers announced a reduction. Quotations on the imported are close to the pre-war level, the present market holding at 25c. per lb., against 24c. for the domestic material during 1919. Yellow prussiate of potash is another item that has fallen in line with prussiate of soda and quotations were considerably higher for spot material. Stocks in resale quarters are very limited and manufacturers seem to be in a well sold up condition.

CHEMICALS

Scattered offerings of *yellow prussiate of soda* are obtainable in the open market and sellers quote from 16@16½c. per lb. The fact that imported shipments which were due to arrive late in November and in the early part of December have not shown up as yet has placed the market in very scant supply. Arrivals were quoted at 15½c. per lb. c.i.f. New York, January-February shipments were held at 15½@15¾c. per lb. The present position of the market is very strong and in all probability will remain so until supplies increase. Sales of *solid caustic soda* for export have gone through at \$3.80 per 100 lb. f.a.s. It was stated some business was transacted down to 3½c. per lb. The irregular condition of the market is keeping spot quotations rather unsettled, but those closely related to the inside workings have no doubt that the market will show signs of real life early in 1922. Producers are taking on contract business over next year at \$2.75 per 100 lb., basis 60 per cent, f.o.b. works. Manufacturers of *bleaching powder* reported sales at \$2.25 per 100 lb., f.o.b. works, in large containers. Textile and paper mills have bought extensively during the past few weeks. The market for imported bleach is very strong and forward shipments are heavily sold as far ahead as February. Spot stocks of imported bleach are quoted at \$2.20 per 100 lb. ex-dock New York. Prices on spot *oxalic acid* have been well maintained at 14½@15c. per lb. Trading is fairly active, with small lot transactions featuring. Producers quote 14@15c. per lb., f.o.b. works, depending upon the brand and quantity involved. Leading factors in domestic *chlorate of soda* quote the market at 7½c. per lb., f.o.b. works. Imported material on the spot market, however, is considerably lower, at prices ranging from 6½@6¾c. per lb. The demand is quite slow and any real business in round lots would undoubtedly bring lower quotations. *Yellow prussiate of potash* is higher and the market reflects to some extent the strength in prussiate of soda. It is very doubtful if better than 23c. per lb. can be done on this commodity, while the majority of sellers are asking all the way up to 24@25c. per lb. for only limited amounts. The red variety is also very scarce and prices range around 29c. per lb. Imported *chlorate of potash* is quoted at prices ranging from 5¼@6c. per lb. In various quarters it was intimated that the market appeared somewhat firmer at the inside quotation. The demand, however, for this chemical has been limited, since the outlet is very narrow in the face of subnormal conditions. This is preventing a rapid distribution of spot stocks, regardless of the attractive prices named. Domestic chlorate remains quotably unchanged at 12c. per lb., f.o.b. works. Imported caustic potash, 88-92 per cent, is moving very slowly and prices are irregular, with offerings heard as low as \$5.40 per 100 lb. Goods on the high seas were obtainable at \$5.35, while shipments were offered at 5½c. per lb. Consumers have not been purchasing any noticeable quantities during the past week and dealers stated that extreme difficulties were found to move any spot stocks. Light *soda ash* has shown very little activity on spot and dealers quote the market for domestic material at \$1.90@\$2 per 100 lb., in single bags, depending upon the quantity. Imported ash on dock was quoted as \$1.70 per 100 lb. and shipment goods at \$1.65. Barrel ash was held at \$2.25@\$2.30 per 100 lb. Producers continue to book contracts over next year at \$1.40 per 100 lb., basis 48 per cent, f.o.b. works, in single bags. Prices on imported *sulphide of soda* have slightly declined. The demand has not shown any marked activity and second hands seemed eager to dispose of stocks at any reasonable price. Sales were reported at 4½@4¾c. per lb., for the 60-62 per cent, fused. Shipment material was held at 4½c. per lb., duty paid, with intimations of lower prices on round lots.

The St. Louis Market

ST. LOUIS, Mo., Dec. 23, 1921.

Trading in the drug and chemical markets shows little real change from the last few weeks, but if anything is a trifle slower. A few small-lot transactions have been recorded, but even in these the movement was irregular and in line with the pre-holiday season. The inventory period and holiday influences have reflected in the market operations, but only to a very small percentage.

Several advances have taken place during the last period on some of the more important items which will give a good stimulating influence for a more stable market. The heavy importations are still of great annoyance to the manufacturers and keep the market very unsettled. However, it is greatly hoped that this obstacle will soon be eliminated, and that the year 1922 will be a prosperous one.

The market on *alkalis* has declined somewhat since our last report. The demand is not great, as the flake has declined from \$5.25 per 100 lb. in single drums to \$4.87½, with the 12½c. differential on 5-drum lots. The carlot material has not changed. The dullness of the market is expected to cause a drop. Solid 76 per cent material is at \$4 per 100 lb. in drums carlots, flakes at \$4.25 per 100 lb. f.o.b. point of production. *Soda ash* has declined somewhat and can now be had at around \$2.90 per 100 lb. barrels, with demand nominal. *Bicarbonate of soda* is moving slowly at about \$2.50 per 100 lb., a decline of 2 to 5c. *Sal soda* is ranging around \$2 per 100 lb., with the market very quiet.

CHEMICAL, DRUGS AND PHARMACEUTICALS

Acetpheneditin is moving in a fair way. Factors have again advanced their price of *acetylsalicylic acid* and a great demand is in evidence. The demand for *bromides* continues to be steady with a very firm market. Demand for *carbon bisulphide* is practically nil. *Creosote* and *guaiacols* are moving in a large way. *Glycerine* has again advanced sharply and now is in good demand at 15½c. in drums. Some contracts are still to be made, and no decline is looked for on this item for some time. Some of the *glycerophosphates* are again coming to life with quite a few inquiries and orders. *Hydroquinone* has taken an upward course and the demand is very brisk. With the rise in the sterling market manufacturers have also revised their prices on *iodides* and a general advance on all *iodide salts* took place on the 10th. *Lithium salts* continues to move quite steadily. The *salicylates* are commanding quite an important position at the present moment. There has been no change in *sulphur* and the market is very dull. *Commercial sulphur*, at \$2 per 100 lb. in 25-bag lots, finds little demand. *Zinc oxide* is moving nicely and maintains the same price level of two weeks previous—that is, 7½c. in barrels, 7¼c. in bags f.o.b. works for standard brands.

ACID

The heavy commercial mineral acids continue to move in a large way. *Citric acid* is not of big importance just at this time. *Pyrogalllic acid* is holding its own. *Tartaric acid* has fallen off quite a bit.

VEGETABLE OILS AND NAVAL STORES

Castor oil is very firm, and the 12½c. price in drums now holds only for quantities of 200 gal. or better; for less than 200 gal. the price is 13c. for the 50-gal. drums. The *linseed oil* market is somewhat firm, and producers are taking contracts only up to May 1, the prevailing price being 70c., basis raw oil. *Turpentine* is gradually climbing and is now 85c. in single barrels, with the usual 4c. differential on 5-bbl. lots.

PAINT MATERIALS

The paint dealers, though usually overly optimistic, are showing signs of life, and some reasonably sized orders have been placed recently. *Barytes* are moving nominally at the old price of \$23.50 per ton. The producers in the St. Louis lithopone market are not turning out much new material as yet, but report all their warehouse stock practically sold up, and are expecting some nice business in the future. *Whiting* can now be had in St. Louis at \$12 per ton, carlots at \$14.50 f.o.b. buyer's door in ton lots.

The Iron and Steel Market

PITTSBURGH, Dec. 23, 1921.

The Steel Corporation's reduction in tubular goods prices, reported a week ago, is followed this week by a reduction in wire products. In each case the reduction was brought about by price shading on the part of independent producers. In each case the reduction made makes market prices somewhat below the average of the cut prices that were ruling.

The reduction in wire products is to a schedule \$5 a ton below the prices ruling prior to the advance of Sept. 12, that advance having been \$2 a ton in plain wire and \$3 a ton in nails and barb wire. The advance held nominally for a time, but it had been preceded by the making of 60-day contracts at the old prices, and when these contracts began to expire, last month, they were found to be renewable. The advance practically slipped away, so that the present reduction is from the old prices, not the advanced prices. The new quotations of the Steel Corporation subsidiary, the American Steel & Wire Co., were first made on Wednesday, Dec. 21, and were of course adopted by independents, being as follows: Plain wire, 2.25c.; galvanized wire, 2.75c.; wire nails, \$2.50; cement coated nails, \$2.15; painted barb wire, 2.65c.; galvanized barb wire, 3.15c.; polished staples, 2.65c.

The average price of wire nails in the 10 years before the war was \$1.80, the low point, struck both in 1911 and in 1914, being \$1.50. Thus nails are now 50 per cent above their previous low point, and it is interesting if not surprising to note that the majority of steel products show quite uniformly at the present time a price 50 per cent above the previous low price. One would, perhaps, expect more variations to be shown between commodities. Bars, shapes and plates are now quotable at 1.50c. in the case of fairly attractive orders, while in December, 1914, the going price on good-sized orders was 1c., the openly quoted market, on lots down to single carloads, being 1.05c.

LIGHT VOLUME OF BUYING

Outside of the price developments in tubular goods and wire products the steel market of the past fortnight has been practically without incident. The volume of buying has been very light, on the whole, and such buying as has occurred has been confined almost entirely to small lots, generally single carloads. All buyers have been particularly conservative in making commitments, not on account of any fresh uncertainties in the situation, but on account of the season of the year. The steel market is always very dull in the second half of December, and that rule holds good even when there is great activity in general.

PRODUCTION RATES

In October production of steel ingots was at the rate of about 23,000,000 gross tons a year, or at about 44 per cent of estimated capacity, and the Steel Corporation and independents respectively operated at very nearly the same percentage rates, in proportion to capacity. In November the Steel Corporation's operating rate increased somewhat, while the independent rate decreased correspondingly. The divergence is now much more marked, as since Dec. 1 the Steel Corporation's operations have been at above 50 per cent, and touched 55 per cent at one time, while the independents have scarcely averaged a 40 per cent rate, and production as a whole is down a trifle from the rate in October and November. A number of mills will probably close the last week of December or the first week of January, partly because they have made a special effort to operate lately, to furnish holiday money to employees. By the latter part of January production is likely to be nearly up to the recent rate, but no very great increase is expected for any time in the first 6 months of the new year.

PIG IRON AND COKE

Pig iron remains quotable at \$20 for bessemer, \$19 for basic and \$19.50 for foundry, at valley furnaces, freight to Pittsburgh being \$1.96.

Connellsville coke is decidedly soft, and market prices might be lower if there were enough inquiry to encourage operators to name their lowest terms. As it is, spot furnace coke is quotable nominally at \$2.90@\$3 and spot foundry at \$3.75@\$4.50, depending on brand.

Formaldehyde, 40 per cent.....lb.	2.50	3.00	2.50	3.00
Fusel oil, ref.....gal.	1.50	1.75	1.50	1.75
Fusel oil, crude.....gal.	1.50	1.75	1.50	1.75
Glauber's salt (see sodium sulphate).....	16	16½	16	16½
Glycerine, C. P. drums extra.....lb.	3.80	3.90	3.80	3.90
Iodine, resublimed.....lb.	12	18	12	18
Iron oxide, red.....lb.	15.00	16.00	17.00	20.00
Iron sulphate (copperas).....ton	10½	12½	10½	12½
Lead acetate.....lb.	15	15½	15½	16½
Lead arsenate, powd.....lb.	15	15½	15½	16½
Lead nitrate.....lb.	15	15½	15½	16½
Litharge.....lb.	08	08½	08½	09
Magnesium carbonate, technical.....lb.	07½	07½	08	09
Magnesium sulphate, U. S. P.....100 lb.	2.65	2.70	2.75	3.00
Magnesium sulphate, technical.....100 lb.	1.10	1.75	1.10	1.75
Methanol, 95%.....gal.	62	63	62	63
Methanol, 97%.....gal.	64	65	64	65
Nickel salt, double.....lb.	12	12½	12	12½
Nickel salt, single.....lb.	14	14½	14	14½
Phosgene (see carbonyl chloride).....	45	46	47	50
Phosphorus, red.....lb.	32	35	32	35
Phosphorus, yellow.....lb.	10½	11	11½	11½
Potassium bichromate.....lb.	10½	11	11½	11½

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar).... lb.	\$.25 - \$.27	\$0.25 - \$0.27
Potassium bromide, granular..... lb.	.15 - .16	.15 - .20
Potassium carbonate, U. S. P..... lb.	.04 - .04	.17 - .20
Potassium carbonate, 80-85%..... lb.	.06 - .06	.05 - .06
Potassium chlorate, crystals..... lb.	.06 - .06	.30 - .35
Potassium cyanide..... lb.	.05 - .05	.06 - .08
Potassium hydroxide (caustic potash).... lb.	.07 - .07	2.90 - 3.00
Potassium iodide..... lb.	.16 - .17	.08 - .09
Potassium nitrate..... lb.	.29 - .29	.18 - .22
Potassium permanganate..... lb.	.23 - .23	.30 - .30
Potassium prussiate, red..... lb.		.24 - .25
Potassium prussiate, yellow..... lb.		
Rochelle salts (see sodium potas tartrate)		
Salammoniac (see ammonium chloride)....		
Sal soda (see sodium carbonate).....		
Salt cake (bulk)..... ton	18.00 - 21.00	
Silver cyanide..... oz.	1.10 - 1.20	
Silver nitrate..... oz.	.45 - .46	
Soda ash, light..... 100 lb.	1.75 - 2.10	2.15 - 2.50
Soda ash, dense..... 100 lb.	2.15 - 2.20	2.25 - 2.50
Sodium acetate..... lb.	.04 - .04	.04 - .05
Sodium bicarbonate..... 100 lb.	2.30 - 2.35	2.40 - 2.75
Sodium bichromate..... lb.	.07 - .08	.08 - .08
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P..... lb.	.04 - .05	.05 - .06
Sodium borate (borax)..... lb.	.05 - .06	.06 - .07
Sodium carbonate (sal soda)..... 100 lb.	1.80 - 1.90	1.95 - 2.15
Sodium carb. rate..... lb.	.06 - .07	.07 - .08
Sodium cyanide..... lb.	.27 - .27	.28 - .30
Sodium fluoride..... lb.	.11 - .12	.12 - .14
Sodium hydroxide (caustic soda)..... 100 lb.	3.75 - 3.80	3.85 - 4.25
Sodium hyposulphite..... lb.	.06 - .06	.03 - .03
Sodium nitrite..... lb.	.25 - .26	.07 - .07
Sodium peroxide, powdered..... lb.	.04 - .04	.27 - .30
Sodium phosphate, dibasic..... lb.	.16 - .16	.04 - .05
Sodium potassium tartrate (Rochelle salts) lb.	.19 - .21	.19 - .21
Sodium prussiate, yellow..... lb.	1.60 - 1.65	.16 - .17
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1.05	1.10 - 1.30
Sodium silicate, solution (60 deg.)..... 100 lb.	2.30 - 2.40	2.45 - 3.00
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.30 - 1.50	1.60 - 2.00
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04 - .04	.04 - .05
Sodium sulphite, crystals..... lb.	.03 - .03	.04 - .04
Sulphur, nitrate, powdered..... lb.	.11 - .12	.12 - .15
Sulphur chloride, red..... lb.	.05 - .06	.06 - .06
Sulphur, crude..... ton	18.00 - 20.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride..... lb.	.09 - .09	.09 - .10
Tin oxide..... lb.	.14 - .14	.39 - .40
Zinc carbonate..... lb.	.09 - .09	.15 - .16
Zinc chloride, gran..... lb.	.42 - .44	.09 - .10
Zinc cyanide..... lb.	.11 - .11	.45 - .47
Zinc dust..... lb.	.07 - .07	.11 - .12
Zinc oxide, XX..... lb.	3.00 - 3.25	.08 - .09
Zinc sulphate..... 100 lb.		3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.30 - .32
Aniline oil, drums extra..... lb.	.17 - .19
Aniline salts..... lb.	.24 - .26
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.35 - 1.45
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.52 - .55
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.) gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3.75 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.30 - .34
Beta-naphthylamine, sublimed..... lb.	1.65 - 1.75
Cresol, U. S. P., in drums (100 lb.)..... lb.	.15 - .16
Ortho-cresol, in drums (100 lb.)..... lb.	.24 - .26
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	.95 - 1.10
Dimethylaniline..... lb.	.40 - .45
Dinitrobenzene..... lb.	.23 - .27
Dinitrochlorobenzene..... lb.	.20 - .25
Dinitronaphthalene..... lb.	.30 - .35
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.25 - .30
Dip oil, 25%, car lots, in drums..... gal.	.30 - .35
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.00 - 1.10
Meta-phenylenediamine..... lb.	1.10 - 1.15
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.65 - 1.70
Naphthalene crushed, in bbls..... lb.	.07 - .08
Naphthalene, flake..... lb.	.07 - .08
Naphthalene, balls..... lb.	.08 - .09
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.15 - .17
Ortho-amidophenol..... lb.	3.00 - 3.10
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.77 - .80
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.40 - 1.45
Para-amidophenol, HCl..... lb.	1.70 - 1.80
Para-dichlorobenzene..... lb.	.12 - .15
Paranitroaniline..... lb.	.77 - .80
Para-nitrotoluene..... lb.	.80 - .85
Para-phenylenediamine..... lb.	1.70 - 1.75
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.37 - .40

Phenol, U. S. P., drums..... lb.	.11 - .15
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.50 - 1.60
Resorcinol, pure..... lb.	2.00 - 2.25
Salicylic acid, tech., in bbls..... lb.	.20 - .21
Salicylic acid, U. S. P..... lb.	.22 - .23
Salol..... lb.	.70 - .72
Solvent naphtha water-white, in drums, 100 gal. gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.27 - .30
Tolidine..... lb.	1.30 - 1.35
Toluidine, mixed..... lb.	.43 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .35

Waxes

Prices based on original packages in large quantities

Bayberry Wax..... lb.	\$0.21 - \$0.22
Beeswax, refined, dark..... lb.	.24 - .25
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.34 - .38
Candelilla wax..... lb.	.24 - .24
Carnauba, No. 1..... lb.	.45 - .46
Carnauba, No. 2, North Country..... lb.	.23 - .24
Carnauba, No. 3, North Country..... lb.	.13 - .14
Japan..... lb.	.21 - .21
Montan, crude..... lb.	.04 - .05
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 - .04
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.03 - .04
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .04
Paraffine waxes, refined, 125 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 133-135 m.p..... lb.	.05 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05 - .05
Stearic acid, single pressed..... lb.	.09 - .09
Stearic acid, double pressed..... lb.	.09 - .09
Stearic acid, triple pressed..... lb.	.10 - .10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.30 - 5.35
Rosin E-I..... 280 lb.	5.40 - 5.50
Rosin K-N..... 280 lb.	6.05 - 6.75
Rosin W. G. W. W..... 280 lb.	7.00 - 7.25
Wood rosin, bbl..... 280 lb.	6.25 - .
Spirits of turpentine..... gal.	.81 - .
Wood turpentine, steam dist..... gal.	.79 - .
Wood turpentine, dest. dist..... gal.	.78 - .
Pine tar pitch, bbl..... 200 lb.	6.00 - .
Tar, kiln burned, bbl. (500 lb.)..... bbl.	9.50 - .
Retort tar, bbl..... 500 lb.	9.50 - .
Rosin oil, first run..... gal.	.36 - .
Rosin oil, second run..... gal.	.39 - .
Rosin oil, third run..... gal.	.46 - .
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	1.90 - .
Pine oil, pure, dest. dist..... gal.	1.50 - .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 - .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 - .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 - .
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 - .
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.25 - .
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.35 - .
Pinewood creosote, ref..... gal.	.52 - .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.37 - .
70-72 deg., steel bbls. (85 lb.)..... gal.	.35 - .
68-70 deg., steel bbls. (85 lb.)..... gal.	.34 - .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.23 - .

Fertilizers

Ammonium sulphate, bulk and d. bags..... 100 lb.	\$2.30 - 2.90
Blood, dried, f.o.b., N. Y..... unit	4.00 - .
Bone, 3 and 50, ground, raw..... ton	30.00 - 32.00
Fish scrap, dom., dried, f.o.b. works..... unit	2.90 - 3.00
Nitrate soda..... 100 lb.	2.30 - 2.35
Tankage, high grade, f.o.b. Chicago..... unit	2.75 - 3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72 p.c..... ton	4.50 - 6.50
Tennessee, 78-80 p.c..... ton	8.50 - 9.00
Potassium muriate, 80 p.c..... ton	34.00 - 35.00
Potassium sulphate..... unit	.70 - 1.00

Crude Rubber

Para-Upriver fine..... lb.	\$0.23 - .23
Upriver coarse..... lb.	.13 - .14
Upriver caucho ball..... lb.	.13 - .13
Plantation—First latex crepe..... lb.	.18 - .18
Ribbed smoked sheets..... lb.	.18 - .19
Brown crepe, thin, clean..... lb.	.15 - .
Amber crepe No. 1..... lb.	.17 - .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 - \$0.10
Castor oil, AA, in bbls..... lb.	.11 - .12
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.13 - .13
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .09
Cocoonut oil, Cochinchina grade, in bbls..... lb.	.10 - .10
Corn oil, crude, in bbls..... lb.	.08 - .08
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07 - .07
Cottonseed oil, summer yellow..... lb.	.08 - .09
Cottonseed oil, winter yellow..... lb.	.09 - .09

Linseed oil, raw, ear lots (domestic).....	gal.	.67	—	.68
Linseed oil, raw, tank ears (domestic).....	gal.	.62	—	.63
Linseed oil, in 5-bbl lots (domestic).....	gal.	.70	—	.71
Olive oil, Denatured.....	gal.	\$1.15	—	\$1.20
Palm, Lagos.....	lb.	.07 ¹ / ₂	—	.07 ¹ / ₂
Palm, Niger.....	lb.	.06 ¹ / ₂	—	.06 ¹ / ₂
Peanut oil, crude, tank ears (f.o.b. mill).....	lb.	.08	—	.08 ¹ / ₂
Peanut oil, refined, in bbls.....	lb.	.11	—	.11 ¹ / ₂
Rapeseed oil, refined, in bbls.....	gal.	.82	—	.83
Rapeseed oil, blown, in bbls.....	gal.	.88	—	.90
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08 ³ / ₄	—	
Soya bean oil, tank ears, f.o.b., Pacific coast.....	lb.	.07 ¹ / ₂	—	

FISH

Light pressed menhaden.....	gal.	\$0.43	—	
Yellow bleached menhaden.....	gal.	.44	—	
White bleached menhaden.....	gal.	.46	—	
Blown menhaden.....	gal.	.48	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$23.00	—	23.50
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	15.00	—	17.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	23.00	—	24.00
Barytes, crude, first grade, Missouri.....	net ton	6.00	—	7.00
Blanc fixe, dry.....	lb.	.04	—	.04 ¹ / ₂
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.14	—	.14 ¹ / ₂
Chalk, Precipitated, domestic, extra light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, domestic, light.....	lb.	.04	—	.04 ¹ / ₂
Chalk, Precipitated, domestic, heavy.....	lb.	.03 ¹ / ₂	—	.04
Chalk, Precipitated, English, extra light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, light.....	lb.	.04 ¹ / ₂	—	.05
Chalk, Precipitated, English, dense.....	lb.	.04	—	.04 ¹ / ₂
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	6.50	—	8.50
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	9.00	—	10.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	13.00	—	20.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	13.00	—	20.00
China clay (kaolin), in ported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), in ported, powdered.....	net ton	25.00	—	30.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Me. es.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Baltimore.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Baltimore.....	net ton	18.00	—	
Fullers earth, in ported, powdered.....	net ton	22.00	—	24.00
Graphite, Ceylon lump, first quality.....	lb.	.05 ¹ / ₂	—	.06 ¹ / ₂
Graphite, Ceylon chip.....	lb.	.04	—	.05
Graphite, high grade amorphous crude.....	lb.	.00 ³ / ₄	—	.02 ¹ / ₂
Kieselguhr, f.o.b. mines, Cal.....	per ton	40.00	—	
Kieselguhr, f.o.b. N.Y.....	per ton	55.00	—	60.00
Magnesite, calcined.....	per ton	50.00	—	65.00
Pumice stone, imported.....	lb.	.03	—	.40
Pumice stone, domestic, lump.....	lb.	.05	—	.05 ¹ / ₂
Pumice stone, domestic, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1 ¹ / ₂ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange line.....	lb.	.68	—	.70
Shellac, orange superline.....	lb.	.78	—	.80
Shellac, A. C. garnet.....	lb.	.58	—	.60
Shellac, T. N.....	lb.	.68	—	.70
Soapstone.....	ton	15.00	—	17.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.25	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	7.50	—	11.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	25.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$50.00	—	
Carborundum refractory brick, 9-in.	1,000	1250.00	—	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	52- 55	—	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30- 32	—	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in ear lots, f.o.b. Eastern shipping points.....	net ton	33- 35	—	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	35- 40	—	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30- 35	—	
Magnesite brick, 9-in. straight.....	net ton	65- 70	—	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77	—	
Magnesite brick, soaps and splits.....	net ton	98	—	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	40- 42	—	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	42- 45	—	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35- 38	—	

Ferro-Alloys

All f.o.b. Works

Ferrocobalt-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Acme Oil Co. of Alabama, recently organized, has had plans prepared for the erection of a local oil works, with initial daily capacity of about 3,000 gal. D. E. Chandler is secretary.

California

SACRAMENTO—The Sacramento Brick Co. is planning for the installation of additional machinery at its plant to develop an annual capacity of about 30,000,000 bricks. The company will also establish a department for the manufacture of roofing tile and other ceramic products. H. H. Bartells is manager.

Georgia

BRUNSWICK—The Ocean Leather Co., 33 New York Ave., Newark, N. J., is perfecting plans for the establishment of a plant at Brunswick for the tanning of shark skins and other fish hides. Alfred Ehrenreich is president.

Florida

JACKSONVILLE—The Florida-Louisiana Refining Co., now being organized with a capital of \$500,000, is planning for the erection of a large oil refinery on local site. H. C. Leete, Jacksonville, heads the organization.

MIAMI—The Pennsylvania Sugar Co., Delaware Ave., Philadelphia, Pa., has acquired a tract of land adjoining its property in this section, totaling about 60,000 acres, and plans to use the portion of the site for a new sugar mill, estimated to cost close to \$500,000, including machinery.

Illinois

HILLSBORO—Fire, Dec. 7, destroyed a portion of the plant of the Schram Glass Mfg. Co., with loss reported at close to \$30,000.

ROCKFORD—The Hess & Hopkins Leather Co. is considering tentative plans for the rebuilding of its 1-story plant, 60 x 115 ft., and proposes to commence work early in the spring. F. L. Morgan is secretary.

CHICAGO—The city of Chicago, architect Charles W. Tallal, is preparing plans for a 2-story pumping station to be erected near Western Ave. and 43d St., in connection with the Western Ave. water tunnel; estimated cost \$3,165,000. The beginning of the work will be dependent upon the appropriation of the 1922 city of Chicago budget.

CHICAGO—The Cole Storage Battery Co., located at 2437 Indiana Ave., is preparing plans for a 1-story addition to its present factory; estimated cost \$30,000.

CHICAGO—The Dental Metal Products Co. is preparing plans for a 2-story mill construction factory, 42x71 ft., and a warehouse 28x42 ft. for the manufacture of dental products. This plant will be located at 7512 Greenwood Ave.; estimated cost \$30,000.

Indiana

INDIANAPOLIS—The Piel Bros. Starch Co., State Life Bldg., is planning for the construction of a 1-story top addition to its plant, 200 x 200 ft. Improvements will be made also in the present plant. The work is estimated to cost about \$50,000. William F. Piel is president.

Louisiana

SHREVEPORT—The United States Sheet & Window Glass Co. is pushing construction on its new local works and expects to occupy the plant at an early date. It is estimated to represent an investment of close to \$1,000,000. It is reported that further additions will be made in the near future.

ALEXANDRIA—W. J. O'Pry, Alexandria, and associates are organizing a new company to establish a local tannery. A building has been purchased for the works, and occupancy will be arranged at an early date.

Maryland

BALTIMORE—The Union Smelting & Refining Co., Charles St., Newark, N. J., has acquired the property at Ostend and Howard Sts., 135 x 155 ft., for a consideration said to be \$31,000. It is proposed to use the site for the erection of a branch plant.

CENTERVILLE—E. S. Valliant & Son, manufacturers of fertilizer products, are arranging for the removal of a portion of their business, now located at Church Hill, and purpose to make Centerville their headquarters. The company operates a large fertilizer plant at Centerville Landing, and will concentrate production to a large extent at this point.

Massachusetts

SALEM—The Park Leather Co., Grove St., has awarded a contract to A. C. Brown, Danvers, Mass., for extensions and improvements in its plant. The work will be commenced at once.

Michigan

SHEBOYGAN—The Union Bag & Paper Co. has work under way on the remodeling of its plant 3-story 60 x 100 ft., estimated to cost about \$100,000. The improvement is being arranged for increased operations and better efficiency in production. G. S. Witham is general superintendent.

DETROIT—The Gagnier Stereotype Foundry Co., 525 Howard Ave., is having plans prepared for the erection of a new 1-story foundry on McKinstry St., estimated to cost about \$50,000. Kasurin Bros., 512 Empire Bldg., are architects. Edmond Gagnier is president.

PONTIAC—The Crodius Steam Pressed Brick Co. has tentative plans under consideration for the construction of a new plant. It is proposed to inaugurate work in the spring of the coming year. C. J. Crawford is president.

OTSEGO—The Mac-Sim-Bar Paper Co. has taken bids for the erection of the proposed new 1-story electric power plant at its mill, to be used for general operating service. It will be 80 x 140 ft., and is estimated to cost close to \$300,000, including machinery. Billingham & Cobb, Press Bldg., Kalamazoo, are architects.

PORT HURON—The Port Huron Sulphite & Paper Co., 1805 Richardson St., has construction under way on a 2-story and basement addition to its plant on Black River St., 70 x 100 ft., estimated to cost about \$50,000. Alfred J. L. Sullivan, 1320 Tenth St., has received the building contract. Edgar Kiefer is president.

Montana

CUT BANK—The Cut Bank Flour Mill Co. is reported to be planning for the rebuilding of the portion of its local plant, recently destroyed by fire with loss estimated at about \$35,000. John Bye is manager.

BAINVILLE—Fire recently destroyed a portion of the flour mill and elevator of the Jennison Mills Co. An official estimate of loss has not been made. It is said that the plant will be rebuilt at once.

New Jersey

METUCHEN—The General Ceramics Co., 50 Church St., New York, has perfected plans for the immediate erection of the proposed addition to its local sanitary ware manufacturing plant, estimated to cost about \$100,000. Dietrich Wertmann, 118 Lexington Ave., New York, is architect.

MATAWAN—Fire, Dec. 16, destroyed a portion of the plant of the Erdman Color Works and the adjoining factory of the Chrome Color Works, operated by the same interests, with loss estimated at about \$85,000, including machinery.

NEWARK—The Miller Oil Products Co., Bloomfield, N. J., has acquired property at 33-39 Ave. A, extending to 135-39 Miller St., for the manufacture of oils, polishes, etc. The lease covers a long term and the company will remove its plant to this location shortly after the first of January. The property comprises a 1-story building, on a lot totaling 100 x 150 ft. A number of improvements are planned.

GARFIELD—Fire, Dec. 12, destroyed a large portion of the plant of the Heyden Chemical Co. of America, Monroe St. and River Road, with loss estimated at close to \$500,000, including machinery. S. H. Chamberlain is president.

ELIZABETH—Fire, Dec. 10, destroyed a portion of the plant of the Darvin Chemical Co., with loss estimated at close to \$75,000. The plant is located on Miller St., and it is proposed to rebuild at an early date.

New York

HUDSON—The Hudson City Steel Co., 233 Broadway, New York, has preliminary plans under way for the erection of a new steel works at Hudson. It is proposed to call for bids early in the spring. Dwight P. Robinson & Co., 125 East Forty-sixth St., New York, are engineers.

North Carolina

LENOIR—T. H. Broyhill and F. H. Coffey, Lenoir, are organizing a new company with capital of \$200,000, for establishment of a local plant for the manufacture of mirrors and other glassware products.

Ohio

CINCINNATI—The Ultra-Marine Co., Huntington, W. Va., manufacturer of bluing, etc., has plans under way for the erection of a 1-story and 2-story plant on site selected at Cincinnati. It is proposed to call for bids late in February. E. C. Baugher is superintendent.

Pennsylvania

JAMISON CITY—The Elk Tanning Co. has construction under way on an addition to its plant, to include a 1-story extension to the beam house. The capacity will be increased.

PHILADELPHIA—F. W. Tunnell & Co., 15 North Fifth St., manufacturers of glue, fertilizers, etc., have filed plans for the creation of a 1-story plant extension.

MARCUS HOOK—The Viscose Co., has work well under way on a 3-story and basement addition to its local plant, estimated to cost about \$150,000. It is planned to occupy the structure for general manufacture at an early date.

Tennessee

CHATTANOOGA—The Independent Glass Co. has awarded a contract to J. W. Pogue, Chattanooga, for the erection of a new 2-story plant, 50 x 195 ft., to be equipped for the manufacture of windshields and other glass products. A. R. Williams is president.

KNOXVILLE—The Knoxville Fertilizer Co. is completing foundations for its new plant in the Vestal section, and will commence the immediate erection of the superstructure. The plant, with equipment, is estimated to cost about \$200,000. J. W. Dean is secretary and treasurer.

BRISTOL—A. D. Reynolds, Bristol and Leroy Park, Greenville, Tenn., are organizing a new company to construct and operate a blast furnace and steel works on a site being selected in eastern Tennessee. It is said that the new plant will cost in excess of \$500,000.

Texas

COLEMAN—J. P. Morris has acquired the local plant of the Brinkley Brick & Tile Co. The new owner purposes to operate the works, and is said to be planning for a number of extensions and improvements.

DALLAS—The O. C. China Novelty & Pottery Co., 1104-6 South Betterton St., has filed plans for the erection of a new 2-story and basement plant, estimated to cost about \$25,000.

HOUSTON—The Humphreys-Pure Oil Co. is reported to be planning for the erection of a new local refinery, with initial capacity of about 30,000 bbl. of oil a day. The refining plant will be operated in connection with the proposed pipe line to be constructed from Mexia, Tex., to the Gulf. The entire project is estimated to cost in excess of \$1,000,000. Col. E. A. Humphreys is president.

CORSICANA—The Corsicana Oil & Refining Co., is planning for the immediate operation of its new local oil refinery, now practically completed. It will be run on a full capacity basis.

Virginia

RICHMOND—The Virginia-Carolina Rubber Co., North Nineteenth Street, will break ground at once for the erection of a new 1-story plant, estimated to cost about \$130,000, and of which amount approximately \$90,000 will be used for the purchase of new machinery and equipment. R. J. Bell is manager.

New Companies

THE PHARMO CHEMICAL Co., Newark, N. J., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are Samuel W. Barlow and Harry S. Neiwirth, 63 New Jersey Railroad Ave., Newark.

THE SOUTH WILLIAMSPORT TANNING Co., South Williamsport, Pa., has been incorporated with a capital of \$24,000, to manufacture leather products. L. R. Plankenhorn, South Williamsport, is treasurer.

THE BOLIVAR REFINING CORP., Bolivar (Allegheny County), N. Y., has been incorporated with a capital of \$350,000, to manufacture refined oil products. The incorporators are H. B. Yerdon, W. E. Sawyer and C. A. Chipman. The company is represented by Bliss & Bliss, Bolivar.

THE CAROLINA FISH & OIL Co., Moorhead City, N. C., has been incorporated with a capital of \$100,000, to manufacture oil products of various kinds. The incorporators are D. W. Wade, E. H. Gorham and J. E. Woodland, Moorhead City.

THE CHICAGO CORE COMPOUND Co., 302 Marquette Bldg., Chicago, Ill., has been incorporated with a capital of \$10,000, to manufacture chemicals, compounds, etc. The incorporators are W. W. Welch, William A. Herron and Thomas G. Lovelace.

THE STANDARD APPROVED PRODUCTS Co., Washington, D. C., has been incorporated under Delaware laws with capital of \$750,000, to manufacture tile, fire-proofing cement and kindred specialties. The incorporators are Albert Pauley, R. J. Michael and Joseph F. Randall, Washington. The company is represented by Horace G. Eastburn, Ford Bldg., Wilmington, Del.

THE NEW YORK FELDSPAR CORP., Rochester, N. Y., has been incorporated with a capital of \$100,000, to operate a feldspar producing and grinding plant. The incorporators are F. G. Kennedy and J. W. B. Bausman. The company is represented by Havens, Mann, Strang & Whipple, attorneys, Rochester.

THE COMMONWEALTH OIL CORP., Union Hill, N. J., has been incorporated with a capital of \$100,000, to manufacture oil products. The incorporators are W. Stanley Coles, George and Herman Koch, 101 Bergenline Ave., Union Hill.

THE MOORE-NORTH RUBBER Co., Fort Worth, Tex., has been organized under state laws to manufacture rubber specialties. The company is headed by J. W. Moore, E. M. North and E. E. Edgar, Fort Worth.

THE MIDWEST GLASS PRODUCTS Co., 112 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of \$500,000, to manufacture glassware of various kinds. The incorporators are O. S. Flath, C. R. W. Peterson and Otto Treulich.

THE ADAMANT RUBBER PRODUCTS Co., New York, N. Y., has been incorporated with a capital of \$500,000, to manufacture rubber goods of various kinds. The incorporators are M. Stabins and B. Weiner. The company is represented by M. P. Schaffer, 1463 Broadway, New York.

THE CITY BRICK Co., Los Angeles, Cal., has been incorporated with a capital of \$100,000, to manufacture brick and other burned clay products. The incorporators are W. R. J. T. and I. L. Simons. The company is represented by Ford & Bodkin, 410 H. W. Hellman Bldg., Los Angeles.

McKECHNIE BROS., INC., Philadelphia, Pa., has been incorporated with a capital of \$150,000, to operate a metal smelting and refining plant. William McKechnie, Bellevue-Stratford Hotel, Philadelphia, is treasurer.

THE ZIRALOY Co., 1227 Calvert Bldg., Baltimore, Md., has been incorporated with a capital of \$50,000, to manufacture metals and metal alloys. The incorporators are Robert E. L. Young and Ferdinand I. Gruebel.

THE NOX-A-MITE CHEMICAL Co., 417 South Dearborn St., Chicago, Ill., has been organized under state laws to manufacture chemicals and chemical byproducts. The incorporators are William F. Ayres, Charles E. Ludington and John F. Gallagher.

THE AMERICAN OIL Co., Hattiesburg, Miss., has been incorporated with a capital of \$100,000, to manufacture petroleum products. The incorporators are A. R. Harbison, J. O. Barron and James A. Swayne, Hattiesburg.

THE NATIONAL FIRREFORM Co., Wilmington, Del., has been incorporated under state laws with capital of \$500,000, to manufacture fiber and pulp products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE EVANSVILLE OIL & GREASE Co., Evansville, Ind., has been incorporated with a capital of \$200,000, to manufacture oils, greases and other lubricants. The incorporators are T. H. Meyer, F. C. Enz and E. H. Schmidt, Evansville.

THE SOUTHERN METAL WORKS, INC., Shelby, N. C., has been incorporated with a capital of \$50,000, to manufacture babbitt metal, solders and kindred products. J. S. Williams is president, and Peyton McSwain, secretary and treasurer, both of Shelby.

THE SOAP & CHEMICAL MFG. Co., Secaucus, N. J., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts, soaps, etc. The incorporators are Emerson C. McVausland, Charles W. Aschenbach and Percy Meebott, 210 Penhorn Ave., Secaucus.

THE UTILITY OIL CORP., Brooklyn, N. Y., has been incorporated with a capital of \$100,000, to manufacture oil products. The incorporators are M. Slavin and S. Margolies. The company is represented by Schwimer & Gempler, 955 Broadway, Brooklyn.

THE RAINBOW OIL Co., Greenville, Miss., has been incorporated with a capital of \$300,000, to manufacture petroleum products. The incorporators are A. R. Harbison and J. O. Barron, Hattiesburg, Miss.

THE GENERAL SEAMLESS TUBE Co., New York, N. Y., has been incorporated under Delaware laws with a capital of \$1,450,000, to manufacture seamless steel tubing and kindred products. The incorporators are James W. Sanders, New York; H. Russ Van Vleck and William Hotchkiss, Montclair, N. J. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE OWENS REFINING Co., Cameron, Tex., has been incorporated with a capital of \$45,000, to manufacture refined petroleum products. The incorporators are John S. Owens, John H. Edwards and E. A. Wallace, Cameron.

THE CHICAGO INSECTICIDE LABORATORY, INC., 3925 Calumet Ave., Chicago, Ill., has been incorporated under state laws with 10 shares of stock, no par value, to manufacture chemicals, insecticides, etc. The incorporators are A. J. Campbell, Albert and Benjamin Heller.

THE CAROLINA SMELTING & REFINING Co., Columbia, S. C., has been organized under state laws to operate a metal smelting and refining plant. A. Morgan is president, and N. Zalmenovitz, secretary-treasurer, both of Columbia.

THE M. C. O. OIL Co., San Francisco, Cal., has been incorporated with a capital of \$2,000,000 under Delaware laws, to manufacture petroleum products. The incorporators are W. R. MacDonald and William H. Jordan, San Francisco. The company is represented by the Corporation Service Co., Wilmington, Del.

THE SHERWOOD PAPER Co., Boston, Mass., has been incorporated with a capital of \$50,000, to manufacture paper specialties. Norman J. MacGaffin, West Medford, Mass., is treasurer.

Industrial Notes

THE QUIGLEY FURNACE SPECIALTIES Co., New York announces that it has added to its staff, as sales manager, Robert L. Warburton, who was formerly associated with the Celite Products Co.

W. LA COSTE NEILSON, heretofore foreign manager for the Norton Co., Worcester, Mass., at London, England, has been elected vice-president and general sales manager of the company. Other officials elected at a recent meeting are: Henry Duckworth as controller and assistant treasurer, Louis E. Saunders as head of the research department and John C. Spence as superintendent of the grinding machine division.

THE EXETER MACHINE WORKS, INC., West Pittston, Pa., makes the following announcements: The appointment of the English Tool & Supply Co. as exclusive sales agent for the Exeter rotary pump line in the Kansas City district; the appointment of Reeves & Skinner Machinery Co. of St. Louis, Mo., as sales agent in the St. Louis district; the appointment of the Hendrie & Bolthoff Mfg. & Supply Co. of Denver, Col., as sales agent in the Denver district; the appointment of the W. P. MacKenzie Co. as sales agent in the Philadelphia and Baltimore districts; the appointment of Buckmaster-Luck-Malochee, Inc., of New Orleans, La., as sales agent in the New Orleans district; the appointment of Vickers & Co. of Seattle, Wash., as sales agent in the Seattle district; the appointment of Hodgeart & Co. of Chicago, Ill., as sales agent in the Chicago district, and the H. M. Stark Machinery Co. of Detroit, Mich., as sales agent in the Detroit district.

Capital Increases, Etc.

THE BINNEY & SMITH Co., 81 Fulton St., New York, N. Y., manufacturer of lamp black, etc., has filed notice of increase in capital from \$250,000 to \$1,250,000.

THE VERNON COTTON OIL Co., Vernon, Tex., has filed notice of increase in capital from \$250,000 to \$300,000.

THE WESTERN PAPER BOX Co., 172 North Green St., Chicago, Ill., has filed notice of increase in capital from \$35,000 to \$100,000.

GODCHAUX SUGARS, INC., 527 Canal St., New Orleans, La., operating a number of sugar refineries, has arranged for a bond issue of \$3,000,000. Charles Godchaux is president.

THE GRAND RAPIDS TIRE & RUBBER CORP., Grand Rapids, Mich., manufacturer of tires and rubber products, has filed notice of increase in capital from \$3,000,000 to \$9,000,000.

THE ROBERT GAIR Co., 350 Madison Ave., New York, manufacturer of paper boxes and other paper products, operating six large plants, has disposed of a bond issue totaling \$4,000,000. George W. Gair is president.

THE TRANSCONTINENTAL OIL Co., 576 Fifth Ave., New York, N. Y., is arranging for a bond issue of \$10,000,000, of which fund about \$7,000,000 will be used for the purchase of new properties, extensions, expansion, etc.

J. G. Leavall has been appointed receiver for the **GENERAL OIL Co.**, Houston, Tex., capitalized at \$20,000,000. The company is said to be solvent but a receivership was deemed advisable.

THE EASTERN MFG. Co., Bangor, Me., operating paper and pulp mills, is arranging for a bond issue to total \$2,500,000, for additional working capital.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE is holding its seventy-fourth meeting at Toronto, Canada. Dec. 26 to 31, 1921.

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

PERKIN MEDAL will be presented to William M. Burton by the Society of Chemical Industry at its meeting Jan. 13 at the Chemists' Club, New York.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.
